### **Features**

#### **CPU Features**

- · Operating Voltage
  - f<sub>SYS</sub>=8MHz: 2.55V~5.5V
- Up to  $0.5\mu s$  instruction cycle with 8MHz system clock at  $V_{DD}$ =5V
- Power down and wake-up functions to reduce power consumption
- · Oscillators
  - Internal RC HIRC
  - Internal 32kHz LIRC
- Multi-mode operation: NORMAL, SLOW, IDLE and SLEEP
- All instructions executed in one to three instruction cycles
- · Table read instructions
- 115 powerful instructions
- 8-level subroutine nesting
- · Bit manipulation instruction

#### **Peripheral Features**

- Flash Program Memory: 4K×16
- RAM Data Memory: 256×8
- True EEPROM Memory: 64×8
- · Watchdog Timer function
- Up to 28 bidirectional I/O lines
- Slew Rate Control for PB0~PB3 Ports output
- Serial Interface Module SPI or I2C
- Software controlled 4-SCOM lines LCD driver with 1/2 bias
- Three pin-shared external interrupts
- Multiple Timer Modules for time measure, input capture, compare match output, PWM output or single pulse output function
- · High Resolution PWM complementary output with dead time control
- · Auto-adjust PWM Duty function
- Two over current protection (OCP) with interrupts
- Two sets of Over/Under voltage protection (OUVP) with interrupts
- USB auto detection function
- Dual Time-Base functions for generation of fixed time interrupt signals
- Multi-channel 12-bit resolution A/D converter
- Low voltage reset function
- · Low voltage detect function
- Flash program memory can be re-programmed up to 10,000 times
- Flash program memory data retention > 10 years
- True EEPROM data memory can be re-programmed up to 100,000 times
- True EEPROM data memory data retention > 10 years

· Package Types

HT45F5N: 28-pin SSOPHT45FH5N: 46-pin QFN

### **General Description**

The devices are a Flash Memory type 8-bit high performance RISC architecture microcontroller. Offering users the convenience of Flash Memory multi-programming features, these devices also include a wide range of functions and features. Other memory includes an area of RAM Data Memory as well as an area of true EEPROM memory for storage of non-volatile data such as serial numbers, calibration data etc.

Analog features include a multi-channel 12-bit A/D converter, two over current protection functions, two sets of over/under voltage protection functions, high resolution PWM output with auto-adjust PWM duty function and an USB devices auto detection function. Multiple and extremely flexible Timer Modules provide timing, pulse generation and PWM generation functions. Protective features such as an internal Watchdog Timer, Low Voltage Reset and Low Voltage Detector coupled with excellent noise immunity and ESD protection ensure that reliable operation is maintained in hostile electrical environments.

These devices also include fully integrated low and high speed oscillators which are flexibly used for different applications. The ability to operate and switch dynamically between a range of operating modes using different clock sources gives users the ability to optimise microcontroller operation and minimise power consumption. Easy communication with the outside world is provided using the internal I<sup>2</sup>C and SPI interface. While the inclusion of flexible I/O programming features, Time-Base functions along with many other features ensure that the devices will find excellent use in different power bank applications.

Circuitry specific to Power Bank applications is also fully integrated within the devices. These include functions such as over and under voltage protection, over current protection and auto detect. These features combine to ensure that a minimum of external components is required to implement Power Bank applications, providing the benefits of reduced component count and reduced circuit board areas.

### **Selection Table**

Most features are common to all devices and the main features distinguishing them are the I/O pin count and Level Shift output pins. The following table summarises the main features of each device.

| Part No. | VDD    | Program<br>Memory | Data<br>Memory | Data<br>EEPROM | I/O | Timer<br>Module | H.R.<br>PWM | A/D        | Auto-adjust PWM Duty |
|----------|--------|-------------------|----------------|----------------|-----|-----------------|-------------|------------|----------------------|
| HT45F5N  | 2.55V~ | 4K×16             | 256×8          | 64×8           | 26  | 10-bit PTM×1    | 2/          | 12-bit×14  | 2                    |
| HT45FH5N | 5.5V   | 4K×10             | 250*6          | 04*0           | 28  | 16-bit STM×1    | V           | 12-DIL* 14 | 2                    |

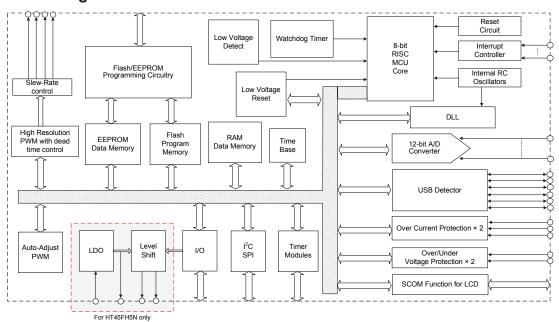

| Part No. | Ref.<br>Voltage | ОСР | OUVP | LDO | Level<br>Shift | PE+ | Q.C<br>2.0 | Stacks | Package |
|----------|-----------------|-----|------|-----|----------------|-----|------------|--------|---------|
| HT45F5N  | ما              | 2   | 0    | _   | _              | _   | _          | 0      | 28SSOP  |
| HT45FH5N | V               | 2   | 2    | 5V  | 2              | √   | √          | 0      | 46QFN   |

Note: H.R. PWM: High Resolution and Complementary PWM Outputs with dead-time control, the duty cycle resolution is 7.8ns when the HIRC is 8MHz.

### **Block Diagram**

# **Pin Assignment**

Note: 1. If the pin-shared pin functions have multiple outputs simultaneously, the desired pin-shared function is determined by the corresponding software control bits.

- The OCDSDA and OCDSCK pins are supplied for the OCDS dedicated pins and as such only available
  for the HT45V5N/HT45VH5N devices which are the OCDS EV chip for theHT45F5N/HT45FH5N
  devices.
- 3. The Exposed Pad, abbreviated as "EP", is connected to ground.
- 4. For the less pin count package type there will be unbounded pins which should be properly configured to avoid unwanted power consumption resulting from floating input conditions. Refer to the "Standby Current Considerations" and "Input/Output Ports" sections.
- 5. For the HT45F5N, PA4, PA5, PD6 and PD7 are not bounded to the external package, whice should be properly configured.

### **Pin Description**

With the exception of the power pins and some relevant transformer control pins, all pins on the device can be referenced by their Port name, e.g. PA0, PA1 etc., which refer to the digital I/O function of the pins. However these Port pins are also shared with other function such as the Analog to Digital Converter, Timer Module pins etc. The function of each pin is listed in the following table, however the details behind how each pin is configured is contained in other sections of the datasheet.

Note that the pin description refers to the largest package size, as a result some pins may not exist on smaller package types.

| Pin Name            | Function | OPT                     | I/T | O/T  | Descriptions   |
|---------------------|----------|-------------------------|-----|------|--|

NMOS: NMOS output;

O/T: Output type; PWR: Power;

CMOS: CMOS output; AN: Analog signal.

### Level Shift Input/Output Relationship and Reset Condition

| Level Shift Output | Level Sh      | nift Input     | Reset State |
|--------------------|---------------|----------------|-------------|
| Level Shift Output | A Input = Low | A Input = High | Reset State |
| AX, BX             | Low           | High           | High        |

| Level Shift Output | Level Sh      | Level Shift Input | Reset State |
|--------------------|---------------|-------------------|-------------|
| Level Still Output | C Input = Low | C Input = High    | Reset State |
| CX, DX             | High          | Low               | Low         |

# **Absolute Maximum Ratings**

| Supply Voltage          | $V_{SS}$ -0.3V to $V_{SS}$ +6.0V |
|-------------------------|----------------------------------|
| Input Voltage           | $V_{SS}$ -0.3V to $V_{DD}$ +0.3V |
| Storage Temperature     | 60°C to 150°C                    |
| Operating Temperature   |                                  |
| I <sub>OL</sub> Total   |                                  |
| I <sub>OH</sub> Total   | 120mA                            |
| Total Power Dissipation | 600mW                            |

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

Note: 1. Load regulation is measured at a constant junction temperature, using pulse testing with a low ON time and is guaranteed up to the maximum power dissipation. Power dissipation is determined by the input/output differential voltage and the output current. Guaranteed maximum power dissipation will not be available over the full input/output range. The maximum allowable power dissipation at any ambient temperature is  $P_D = (T_{J(MAX)} - T_a)/\theta_{JA}$ .

2. Dropout voltage is defined as the input voltage minus the output voltage that produces a 2% change in the output voltage from the value at  $V_{IN}=V_{OUT}+2V$ .

### **System Architecture**

A key factor in the high-performance features of the Holtek range of microcontrollers is attributed to their internal system architecture. The device takes advantage of the usual features found within RISC microcontrollers providing increased speed of operation and enhanced performance. The pipelining scheme is implemented in such a way that instruction fetching and instruction execution are overlapped, hence instructions are effectively executed in one or two cycles for most of the standard or extended instructions respectively. The exceptions to this are branch or call instructions which need one more cycle. An 8-bit wide ALU is used in practically all instruction set operations, which carries out arithmetic operations, logic operations, rotation, increment, decrement, branch decisions, etc. The internal data path is simplified by moving data through the Accumulator and the ALU. Certain internal registers are implemented in the Data Memory and can be directly or indirectly addressed. The simple addressing methods of these registers along with additional architectural features ensure that a minimum of external components is required to provide a functional I/O and A/D control system with maximum reliability and flexibility. This makes the device suitable for low-cost, high-volume production for controller applications.

#### **Clocking and Pipelining**

The main system clock, derived from either the HIRC or LIRC oscillator is subdivided into four internally generated non-overlapping clocks, T1~T4. The Program Counter is incremented at the beginning of the T1 clock during which time a new instruction is fetched. The remaining T2~T4 clocks carry out the decoding and execution functions. In this way, one T1~T4 clock cycle forms one instruction cycle. Although the fetching and execution of instructions takes place in consecutive instruction cycles, the pipelining structure of the microcontroller ensures that instructions are effectively executed in one instruction cycle. The exception to this are instructions where the contents of the Program Counter are changed, such as subroutine calls or jumps, in which case the instruction will take one more instruction cycle to execute.

System Clocking and Pipelining

For instructions involving branches, such as jump or call instructions, two machine cycles are required to complete instruction execution. An extra cycle is required as the program takes one cycle to first obtain the actual jump or call address and then another cycle to actually execute the branch. The requirement for this extra cycle should be taken into account by programmers in timing sensitive applications.

Instruction Fetching

### **Program Counter**

During program execution, the Program Counter is used to keep track of the address of the next instruction to be executed. It is automatically incremented by one each time an instruction is executed except for instructions, such as "JMP" or "CALL" that demands a jump to a non-consecutive Program Memory address. Only the lower 8 bits, known as the Program Counter Low Register, are directly addressable by the application program.

When executing instructions requiring jumps to non-consecutive addresses such as a jump instruction, a subroutine call, interrupt or reset, etc., the microcontroller manages program control by loading the required address into the Program Counter. For conditional skip instructions, once the condition has been met, the next instruction, which has already been fetched during the present instruction execution, is discarded and a dummy cycle takes its place while the correct instruction is obtained.

| Program Counter           |              |  |  |  |  |
|---------------------------|--------------|--|--|--|--|
| Program Counter High Byte | PCL Register |  |  |  |  |
| PC11~PC8                  | PCL7~PCL0    |  |  |  |  |

**Program Counter** 

The lower byte of the Program Counter, known as the Program Counter Low register or PCL, is available for program control and is a readable and writeable register. By transferring data directly into this register, a short program jump can be executed directly; however, as only this low byte is available for manipulation, the jumps are limited to the present page of memory that is 256 locations. When such program jumps are executed it should also be noted that a dummy cycle will be inserted. Manipulating the PCL register may cause program branching, so an extra cycle is needed to pre-fetch.

### Stack

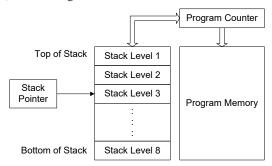

This is a special part of the memory which is used to save the contents of the Program Counter only. The stack is neither readable nor writeable. The activated level is indexed by the Stack Pointer, and is neither readable nor writeable. At a subroutine call or interrupt acknowledge signal, the contents of the Program Counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction, RET or RETI, the Program Counter is restored to its previous value from the stack. After a device reset, the Stack Pointer will point to the top of the stack.

If the stack is full and an enabled interrupt takes place, the interrupt request flag will be recorded but the acknowledge signal will be inhibited. When the Stack Pointer is decremented, by RET or RETI, the interrupt will be serviced. This feature prevents stack overflow allowing the programmer to use the structure more easily. However, when the stack is full, a CALL subroutine instruction can still be executed which will result in a stack overflow. Precautions should be taken to avoid such cases which might cause unpredictable program branching.

Rev. 1.50 24 October 26, 2023

If the stack is overflow, the first Program Counter save in the stack will be lost.

### Arithmetic and Logic Unit - ALU

The arithmetic-logic unit or ALU is a critical area of the microcontroller that carries out arithmetic and logic operations of the instruction set. Connected to the main microcontroller data bus, the ALU receives related instruction codes and performs the required arithmetic or logical operations after which the result will be placed in the specified register. As these ALU calculation or operations may result in carry, borrow or other status changes, the status register will be correspondingly updated to reflect these changes. The ALU supports the following functions:

- Arithmetic operations: ADD, ADDM, ADC, ADCM, SUB, SUBM, SBC, SBCM, DAA, LADD, LADDM, LADC, LADCM, LSUB, LSUBM, LSBC, LSBCM, LDAA
- Logic operations: AND, OR, XOR, ANDM, ORM, XORM, CPL, CPLA, LAND, LANDM, LOR, LORM, LXOR, LXORM, LCPL, LCPLA
- Rotation: RRA, RR, RRCA, RRC, RLA, RL, RLCA, RLC, LRR, LRRA, LRRCA, LRRC, LRLA, LRL, LRLCA, LRLC
- Increment and Decrement: INCA, INC, DECA, DEC, LINCA, LINC, LDECA, LDEC
- Branch decision: JMP, SZ, SZA, SNZ, SIZ, SDZ, SIZA, SDZA, CALL, RET, RETI, LSNZ, LSZ, LSZA, LSIZ, LSIZ, LSDZ, LSDZA

### Flash Program Memory

The Program Memory is the location where the user code or program is stored. For this device the Program Memory is Flash type, which means it can be programmed and re-programmed a large number of times, allowing the user the convenience of code modification on the same device. By using the appropriate programming tools, this Flash device offers users the flexibility to conveniently debug and develop their applications while also offering a means of field programming and updating.

#### Structure

The Program Memory has a capacity of 4K×16 bits. The Program Memory is addressed by the Program Counter and also contains data, table information and interrupt entries. Table data, which can be setup in any location within the Program Memory, is addressed by a separate table pointer register.

**Program Memory Structure** 

### **Special Vectors**

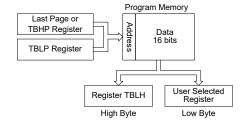

Within the Program Memory, certain locations are reserved for the reset and interrupts. The location 0000H is reserved for use by the device reset for program initialisation. After a device reset is initiated, the program will jump to this location and begin execution.

#### Look-up Table

Any location within the Program Memory can be defined as a look-up table where programmers can store fixed data. To use the look-up table, the table pointer must first be setup by placing the address of the look up data to be retrieved in the table pointer register, TBLP and TBHP. These registers define the total address of the look-up table.

After setting up the table pointer, the table data can be retrieved from the Program Memory using the corresponding table read instruction such as "TABRD [m]" or "TABRDL [m]" respectively when the memory [m] is located in sector 0. If the memory [m] is located in other sectors, the data can be retrieved from the program memory using the corresponding extended table read instruction such as "LTABRD [m]" or "LTABRDL [m]" respectively. When the instruction is executed, the lower order table byte from the Program Memory will be transferred to the user defined Data Memory register [m] as specified in the instruction. The higher order table data byte from the Program Memory will be transferred to the TBLH special register.

The accompanying diagram illustrates the addressing data flow of the look-up table.

Rev. 1.50 26 October 26, 2023

### **Table Program Example**

The following example shows how the table pointer and table data is defined and retrieved from the microcontroller. This example uses raw table data located in the Program Memory which is stored there using the ORG statement. The value at this ORG statement is "0F00H" which refers to the start address of the last page within the 4K Program Memory of the microcontroller. The table pointer low byte register is setup here to have an initial value of "06H". This will ensure that the first data read from the data table will be at the Program Memory address "F06H" or 6 locations after the start of the specified page. Note that the value for the table pointer is referenced to the first address specified by TBLP and TBHP if the "TABRD [m]" or "LTABRD [m]" instruction is being used. The high byte of the table data which in this case is equal to zero will be transferred to the TBLH register automatically when the "TABRD [m]" or "LTABRD [m]" instruction is executed.

Because the TBLH register is a read/write register and can be restored, care should be taken to ensure its protection if both the main routine and Interrupt Service Routine use table read instructions. If using the table read instructions, the Interrupt Service Routines may change the value of the TBLH and subsequently cause errors if used again by the main routine. As a rule it is recommended that simultaneous use of the table read instructions should be avoided. However, in situations where simultaneous use cannot be avoided, the interrupts should be disabled prior to the execution of any main routine table-read instructions. Note that all table related instructions require two instruction cycles to complete their operation.

#### **Table Read Program Example**

```
tempreg1 db ?
                  ; temporary register #1
tempreg2 db ?
                  ; temporary register #2
mov a,06h
                  ; initialise low table pointer - note that this address is
referenced

dc 00Ah, 00Bh, 00Ch, 00Dh, 00Eh, 00Fh, 01Ah, 01Bh
```

### In Circuit Programming - ICP

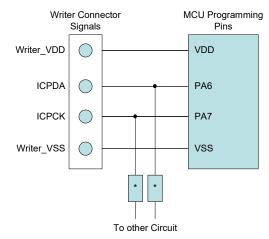

The provision of Flash type Program Memory provides the user with a means of convenient and easy upgrades and modifications to their programs on the same device. As an additional convenience, Holtek has provided a means of programming the microcontroller in-circuit using a 4-pin interface. This provides manufacturers with the possibility of manufacturing their circuit boards complete with a programmed or un-programmed microcontroller, and then programming or upgrading the program at a later stage. This enables product manufacturers to easily keep their manufactured products supplied with the latest program releases without removal and re-insertion of the device.

The Holtek Flash MCU to Writer Programming Pin correspondence table is as follows:

| Holtek Writer Pins | MCU Programming Pins | Pin Description                 |  |
|--------------------|----------------------|---------------------------------|--|
| ICPDA              | PA6                  | Programming Serial Data/Address |  |
| ICPCK              | PA7                  | Programming Clock               |  |
| VDD                | VDD                  | Power Supply                    |  |

The Program Memory can be programmed serially in-circuit using this 4-wire interface. Data is downloaded and uploaded serially on a single pin with an additional line for the clock. Two additional lines are required for the power supply. The technical details regarding the in-circuit programming of the device are beyond the scope of this document and will be supplied in supplementary literature.

During the programming process, taking control of the ICPDA and ICPCK pins for data and clock programming purposes. The user must there take care to ensure that no other outputs are connected to these two pins.

Note: \* may be resistor or capacitor. The resistance of \* must be greater than  $1k\Omega$  or the capacitance of \* must be less than 1nF.

### On Chip Debug Support - OCDS

There is an EV chip named HT45V5N/HT45VH5N which is used to emulate the HT45F5N/HT45FH5N device. The EV chip device also provides an "On-Chip Debug" function to debug the real MCU device during the development process. The EV chip and the real MCU device are almost functionally compatible except for "On-Chip Debug" function. Users can use the EV chip device to emulate the real chip device behavior by connecting the OCDSDA and OCDSCK pins to the Holtek HT-IDE development tools. The OCDSDA pin is the OCDS Data/Address input/output pin while the OCDSCK pin is the OCDS clock input pin. When users use the EV chip for debugging, other functions which are shared with the OCDSDA and OCDSCK pins in the device will have no effect in the EV chip. However, the two OCDS pins which are pin-shared with the ICP programming pins are still used as the Flash Memory programming pins for ICP. For more detailed OCDS information, refer to the corresponding document named "Holtek e-Link for 8-bit MCU OCDS User's Guide".

| Holtek e-Link Pins | EV Chip Pins | Pin Description                                 |
|--------------------|--------------|---|
| OCDSDA             | OCDSDA       | On-Chip Debug Support Data/Address input/output |
| OCDSCK             | OCDSCK       | On-Chip Debug Support Clock input               |
| VDD                | VDD          | Power Supply                                    |
| VSS                | VSS          | Ground  |

### **RAM Data Memory**

The Data Memory is a volatile area of 8-bit wide RAM internal memory and is the location where temporary information is stored.

Categorized into two types, the first of these is an area of RAM where special function registers are located. These registers have fixed locations and are necessary for correct operation of the device. Many of these registers can be read from and written to directly under program control, however, some remain protected from user manipulation. The second area of Data Memory is reserved for general purpose use. All locations within this area are read and write accessible under program control.

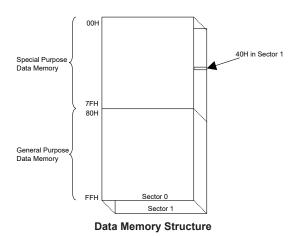

#### **Structure**

The overall Data Memory is subdivided into several sectors, all of which are implemented in 8-bit wide RAM. Each of the Data Memory Sector is categorized into two types, the special Purpose Data Memory and the General Purpose Data Memory. The Special Purpose Data Memory registers are accessible in all sectors, with the exception of the EEC register at address 40H, which is only accessible in sector 1. Switching between the different Data Memory sectors is achieved by setting the Memory Pointers to the correct value. The start address of the Data Memory is the address 00H.

| Special Purpose     | General Purpose Data Memory |                   |  |  |
|---------------------|-----------------------------|-------------------|--|--|
| Data Memory Address | Capacity                    | Address           |  |  |
| Sector 0: 00H~7FH   | 256×8                       | Sector 0: 80H~FFH |  |  |
| Sector 1: 00H~7FH   | 200*0                       | Sector 1: 80H~FFH |  |  |

### **Data Memory Addressing**

For these devices that support the extended instructions, there is no Bank Pointer for Data Memory addressing. For Data Memory the desired Sector is pointed by the MP1H or MP2H register and the certain Data Memory address in the selected sector is specified by the MP1L or MP2L register when using indirect addressing access.

Direct Addressing can be used in all sectors using the corresponding instruction which can address all available data memory space. For the accessed data memory which is located in any data memory sectors except sector 0, the extended instructions can be used to access the data memory instead of using the indirect addressing access. The main difference between standard instructions and extended instructions is that the data memory address "m" in the extended instructions can be composed of 9 bits, the high byte indicates a sector and the low byte indicates a specific address.

### **General Purpose Data Memory**

All microcontroller programs require an area of read/write memory where temporary data can be stored and retrieved for use later. It is this area of RAM memory that is known as General Purpose Data Memory. This area of Data Memory is fully accessible by the user programing for both reading and writing operations. By using the bit operation instructions individual bits can be set or reset under program control giving the user a large range of flexibility for bit manipulation in the Data Memory.

#### **Special Purpose Data Memory**

This area of Data Memory is where registers, necessary for the correct operation of the microcontroller, are stored. Most of the registers are both readable and writeable but some are protected and are readable only, the details of which are located under the relevant Special Function Register section. Note that for locations that are unused, any read instruction to these addresses will return the value "00H".

**Special Purpose Data Memory** 

### **Special Function Register Description**

Most of the Special Function Register details will be described in the relevant functional section, however several registers require a separate description in this section.

### Indirect Addressing Registers - IAR0, IAR1, IAR2

The Indirect Addressing Registers, IAR0, IAR1 and IAR2, although having their locations in normal RAM register space, do not actually physically exist as normal registers. The method of indirect addressing for RAM data manipulation uses these Indirect Addressing Registers and Memory Pointers, in contrast to direct memory addressing, where the actual memory address is specified. Actions on the IAR0, IAR1 and IAR2 registers will result in no actual read or write operation to these registers but rather to the memory location specified by their corresponding Memory Pointers, MP0, MP1L/MP1H or MP2L/MP2H. Acting as a pair, IAR0 and MP0 can together access data only from Sector 0 while the IAR1 register together with the MP1L/MP1H register pair and IAR2 register together with the MP2L/MP2H register pair can access data from any Data Memory Sector. As the Indirect Addressing Registers are not physically implemented, reading the Indirect Addressing Registers will return a result of "00H" and writing to the registers will result in no operation.

### Memory Pointers - MP0, MP1L, MP1H, MP2L, MP2H

Five Memory Pointers, known as MP0, MP1L, MP1H, MP2L, MP2H, are provided. These Memory Pointers are physically implemented in the Data Memory and can be manipulated in the same way as normal registers providing a convenient way with which to address and track data. When any operation to the relevant Indirect Addressing Registers is carried out, the actual address that the microcontroller is directed to is the address specified by the related Memory Pointer. MP0, together with Indirect Addressing Register, IAR0, are used to access data from Sector 0, while MP1L/MP1H together with IAR1 and MP2L/MP2H together with IAR2 are used to access data from all sectors according to the corresponding MP1H or MP2H register. Direct Addressing can be used in all sectors using the corresponding instruction which can address all available data memory space.

The following example shows how to clear a section of four Data Memory locations already defined as locations adres1 to adres4.

#### Indirect Addressing Program Example 1

```
data .section 'data'
adres1 db?
adres2 db?
adres3 db?
adres4 db?
block db?
code .section at 0 'code'
org 00h
start:
mov a, 04h
                           ; setup size of block
mov block, a
mov a, offset adres1
                            ; Accumulator loaded with first RAM address
                            ; setup memory pointer with first RAM address
mov mp0, a
loop:
clr IAR0
                            ; clear the data at address defined by MPO
inc mp0
                            ; increment memory pointer
sdz block
                            ; check if last memory location has been cleared
jmp loop
continue:
```

Rev. 1.50 32 October 26, 2023

#### **Indirect Addressing Program Example 2**

```
data .section 'data'
adres1 db?
adres2 db?
adres3 db?
adres4 db?
block db?
code .section at 0 'code'
org 00h
start:
                        ; setup size of block
mov a, 04h
mov block, a
mov a, 01h
                        ; setup the memory sector
mov mp1h, a
mov a, offset adres1 ; Accumulator loaded with first RAM address
mov mp11, a
                        ; setup memory pointer with first RAM address
loop:
clr IAR1
                        ; clear the data at address defined by MP1L
inc mp11
                         ; increment memory pointer MP1L
sdz block
                         ; check if last memory location has been cleared
jmp loop
continue:
```

The important point to note here is that in the example shown above, no reference is made to specific Data Memory addresses.

#### **Direct Addressing Program Example using extended instructions**

```
data .section 'data'
temp db?
code .section at 0 'code'
org 00h
start:
                         ; move [m] data to acc
lmov a, [m]
lsub a, [m+1]
                         ; compare [m] and [m+1] data
snz c
                         ; [m]>[m+1]?
jmp continue
                         ; no
lmov a, [m]
                         ; yes, exchange [m] and [m+1] data
mov temp, a
lmov a, [m+1]
lmov [m], a
mov a, temp
lmov [m+1], a
continue:
```

Note: here "m" is a data memory address located in any data memory sectors. For example, m=1F0H, it indicates address 0F0H in Sector 1.

#### **Accumulator - ACC**

The Accumulator is central to the operation of any microcontroller and is closely related with operations carried out by the ALU. The Accumulator is the place where all intermediate results from the ALU are stored. Without the Accumulator it would be necessary to write the result of each calculation or logical operation such as addition, subtraction, shift, etc., to the Data Memory resulting in higher programming and timing overheads. Data transfer operations usually involve the temporary storage function of the Accumulator; for example, when transferring data between one user-defined register and another, it is necessary to do this by passing the data through the Accumulator as no direct transfer between two registers is permitted.

### Program Counter Low Register - PCL

To provide additional program control functions, the low byte of the Program Counter is made accessible to programmers by locating it within the Special Purpose area of the Data Memory. By manipulating this register, direct jumps to other program locations are easily implemented. Loading a value directly into this PCL register will cause a jump to the specified Program Memory location, however, as the register is only 8-bit wide, only jumps within the current Program Memory page are permitted. When such operations are used, note that a dummy cycle will be inserted.

#### Look-up Table Registers - TBLP, TBHP, TBLH

These three special function registers are used to control operation of the look-up table which is stored in the Program Memory. TBLP and TBHP are the table pointers and indicate the location where the table data is located. Their value must be setup before any table read commands are executed. Their value can be changed, for example using the "INC" or "DEC" instructions, allowing for easy table data pointing and reading. TBLH is the location where the high order byte of the table data is stored after a table read data instruction has been executed. Note that the lower order table data byte is transferred to a user defined location.

#### Status Register - STATUS

This 8-bit register contains the SC flag, CZ flag, zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF), and watchdog time-out flag (TO). These arithmetic/logical operation and system management flags are used to record the status and operation of the microcontroller.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PDF flag. In addition, operations related to the status register may give different results due to the different instruction operations. The TO flag can be affected only by a system power-up, a WDT time-out or by executing the "CLR WDT" or "HALT" instruction. The PDF flag is affected only by executing the "HALT" or "CLR WDT" instruction or during a system power-up.

The Z, OV, AC, C, SC and CZ flags generally reflect the status of the latest operations.

- C is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
- AC is set if an operation results in a carry out of the low nibbles in addition, or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
- Z is set if the result of an arithmetic or logical operation is zero; otherwise Z is cleared.
- OV is set if an operation results in a carry into the highest-order bit but not a carry out of the highest-order bit, or vice versa; otherwise OV is cleared.

Rev. 1.50 34 October 26, 2023

- PDF is cleared by a system power-up or executing the "CLR WDT" instruction. PDF is set by executing the "HALT" instruction.
- TO is cleared by a system power-up or executing the "CLR WDT" or "HALT" instruction. TO is set by a WDT time-out.
- CZ is the operational result of different flags for different instructions. Refer to register definitions for more details.
- SC is the result of the "XOR" operation which is performed by the OV flag and the MSB of the current instruction operation result.

In addition, on entering an interrupt sequence or executing a subroutine call, the status register will not be pushed onto the stack automatically. If the contents of the status registers are important and if the subroutine can corrupt the status register, precautions must be taken to correctly save it.

#### STATUS Register

| Bit  | 7  | 6  | 5  | 4   | 3   | 2   | 1   | 0   |
|------|----|----|----|-----|-----|-----|-----|-----|
| Name | SC | CZ | TO | PDF | OV  | Z   | AC  | С   |
| R/W  | R  | R  | R  | R   | R/W | R/W | R/W | R/W |
| POR  | Х  | Х  | 0  | 0   | Х   | Х   | Х   | Х   |

"x" unknown

- Bit 7 SC: XOR operation result performed by the OV flag and the MSB of the instruction operation result.
- Bit 6 CZ: Operational result of different flags for different instructions.

For SUB/SUBM/LSUB/LSUBM instructions, the CZ flag is equal to the Z flag.

For SBC/SBCM/LSBC/LSBCM instructions, the CZ flag is the "AND" operation result which is performed by the previous operation CZ flag and current operation zero flag.

For other instructions, the CZ flag will not be affected.

- Bit 5 TO: Watchdog Time-Out flag
  - 0: After power up or executing the "CLR WDT" or "HALT" instruction
  - 1: A watchdog time-out occurred.
- Bit 4 **PDF**: Power down flag
  - 0: After power up or executing the "CLR WDT" instruction
  - 1: By executing the "HALT" instruction
- Bit 3 **OV**: Overflow flag
  - 0: No overflow
  - An operation results in a carry into the highest-order bit but not a carry out of the highest-order bit or vice versa.
- Bit 2 **Z**: Zero flag
  - 0: The result of an arithmetic or logical operation is not zero
  - 1: The result of an arithmetic or logical operation is zero
- Bit 1 AC: Auxiliary flag
  - 0: No auxiliary carry
  - 1: An operation results in a carry out of the low nibbles in addition, or no borrow from the high nibble into the low nibble in subtraction
- Bit 0 C: Carry flag
  - 0: No carry-out
  - 1: An operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation

C is also affected by a rotate through carry instruction.

### **EEPROM Data Memory**

These devices contain an area of internal EEPROM Data Memory. EEPROM, which stands for Electrically Erasable Programmable Read Only Memory, is by its nature a non-volatile form of re-programmable memory, with data retention even when its power supply is removed. By incorporating this kind of data memory, a whole new host of application possibilities are made available to the designer. The availability of EEPROM storage allows information such as product identification numbers, calibration values, specific user data, system setup data or other product information to be stored directly within the product microcontroller. The process of reading and writing data to the EEPROM memory has been reduced to a very trivial affair.

### **EEPROM Data Memory Structure**

The EEPROM Data Memory capacity is 64×8 bits. Unlike the Program Memory and RAM Data Memory, the EEPROM Data Memory is not directly mapped into memory space and is therefore not directly addressable in the same way as the other types of memory. Read and Write operations to the EEPROM are carried out in single byte operations using an address and a data register in Sector 0, 1 and a single control register in only Sector 1.

### **EEPROM Registers**

Three registers control the overall operation of the internal EEPROM Data Memory. These are the address register, EEA, the data register, EED and a single control register, EEC. As both the EEA and EED registers are located in Sector 0, they can be directly accessed in the same was as any other Special Function Register. The EEC register however, being located in only Sector 1, cannot be addressed directly and only can be read from or written to indirectly using the MP1L/MP1H or MP2L/MP2H Memory Pointer and Indirect Addressing Register, IAR1/IAR2. Because the EEC control register is located at address 40H in Sector 1, the MP1L or MP2L Memory Pointer must first be set to the value 40H and the MP1H or MP2H Memory Pointer high byte set to the value, 01H, before any operations on the EEC register are executed.

| Register | Bit |    |    |    |      |    |      |    |  |
|----------|-----|----|----|----|------|----|------|----|--|
| Name     | 7   | 6  | 5  | 4  | 3    | 2  | 1    | 0  |  |
| EEA      | _   | _  | D5 | D4 | D3   | D2 | D1   | D0 |  |
| EED      | D7  | D6 | D5 | D4 | D3   | D2 | D1   | D0 |  |
| EEC      | _   | _  | _  | _  | WREN | WR | RDEN | RD |  |

Bit 7~4 Unimplemented, read as "0"

Bit 3 WREN: Data EEPROM Write Enable

0: Disable 1: Enable

This is the Data EEPROM Write Enable Bit which must be set high before Data EEPROM write operations are carried out. Clearing this bit to zero will inhibit Data EEPROM write operations.

Bit 2 WR: EEPROM Write Control

0: Write cycle has finished1: Activate a write cycle

This is the Data EEPROM Write Control Bit and when set high by the application program will activate a write cycle. This bit will be automatically reset to zero by the hardware after the write cycle has finished. Setting this bit high will have no effect if the WREN has not first been set high.

Bit 1 RDEN: Data EEPROM Read Enable

0: Disable

1: Enable

This is the Data EEPROM Read Enable Bit which must be set high before Data EEPROM read operations are carried out. Clearing this bit to zero will inhibit Data EEPROM read operations.

Bit 0 **RD**: EEPROM Read Control

0: Read cycle has finished

1: Activate a read cycle

This is the Data EEPROM Read Control Bit and when set high by the application program will activate a read cycle. This bit will be automatically reset to zero by the hardware after the read cycle has finished. Setting this bit high will have no effect if the RDEN has not first been set high.

Note: The WREN, WR, RDEN and RD cannot be set high at the same time in one instruction. The WR and RD cannot be set high at the same time.

Rev. 1.50 37 October 26, 2023

### Reading Data from the EEPROM

To read data from the EEPROM, the read enable bit, RDEN, in the EEC register must first be set high to enable the read function. The EEPROM address of the data to be read must then be placed in the EEA register. If the RD bit in the EEC register is now set high, a read cycle will be initiated. Setting the RD bit high will not initiate a read operation if the RDEN bit has not been set. When the read cycle terminates, the RD bit will be automatically cleared to zero, after which the data can be read from the EED register. The data will remain in the EED register until another read or write operation is executed. The application program can poll the RD bit to determine when the data is valid for reading.

## Writing Data to the EEPROM

To write data to the EEPROM, the EEPROM address of the data to be written must first be placed in the EEA register and the data placed in the EED register. Then the write enable bit, WREN, in the EEC register must first be set high to enable the write function. After this, the WR bit in the EEC register must be immediately set high to initiate a write cycle. These two instructions must be executed consecutively. The global interrupt bit EMI should also first be cleared before implementing any write operations, and then set again after the write cycle has started. Note that setting the WR bit high will not initiate a write cycle if the WREN bit has not been set. As the EEPROM write cycle is controlled using an internal timer whose operation is asynchronous to microcontroller system clock, a certain time will elapse before the data will have been written into the EEPROM. Detecting when the write cycle has finished can be implemented either by polling the WR bit in the EEC register or by using the EEPROM interrupt. When the write cycle terminates, the WR bit will be automatically cleared to zero by the microcontroller, informing the user that the data has been written to the EEPROM. The application program can therefore poll the WR bit to determine when the write cycle has ended.

## **Write Protection**

Protection against inadvertent write operation is provided in several ways. After the device is powered-on the Write Enable bit in the control register will be cleared preventing any write operations. Also at power-on the Memory Pointer high byte register, MP1H or MP2H, will be reset to zero, which means that Data Memory Sector 0 will be selected. As the EEPROM control register is located in Sector 1, this adds a further measure of protection against spurious write operations. During normal program operation, ensuring that the Write Enable bit in the control register is cleared will safeguard against incorrect write operations.

### **EEPROM Interrupt**

The EEPROM write interrupt is generated when an EEPROM write cycle has ended. The EEPROM interrupt must first be enabled by setting the DEE bit in the relevant interrupt register. However as the EEPROM is contained within a Multi-function Interrupt, the associated multi-function interrupt enable bit must also be set. When an EEPROM write cycle ends, the DEF request flag and its associated multi-function interrupt request flag will both be set. If the global, EEPROM and Multi-function interrupts are enabled and the stack is not full, a jump to the associated Multi-function Interrupt vector will take place. When the interrupt is serviced only the Multi-function interrupt flag will be automatically reset, the EEPROM interrupt flag must be manually reset by the application program. More details can be obtained in the Interrupt section.

Rev. 1.50 38 October 26, 2023

### **Programming Considerations**

Care must be taken that data is not inadvertently written to the EEPROM. Protection can be enhanced by ensuring that the Write Enable bit is normally cleared to zero when not writing. Also the Memory Pointer high byte register, MP1H or MP2H, could be normally cleared to zero as this would inhibit access to Sector 1 where the EEPROM control register exist. Although certainly not necessary, consideration might be given in the application program to the checking of the validity of new write data by a simple read back process.

When writing data the WR bit must be set high immediately after the WREN bit has been set high, to ensure the write cycle executes correctly. The global interrupt bit EMI should also be cleared before a write cycle is executed and then re-enabled after the write cycle starts. Note that the device should not enter the IDLE or SLEEP mode until the EEPROM read or write operation is totally complete. Otherwise, the EEPROM read or write operation will fail.

### **Programming Examples**

#### Reading data from the EEPROM - polling method

```
MOV A, EEPROM ADRES
                        ; user defined address
MOV EEA, A
MOV A, 040H
                        ; setup memory pointer MP1L
MOV MP1L, A
                        ; MP1 points to EEC register
MOV A, 01H
                         ; setup memory pointer MP1H
MOV MP1H, A
SET IAR1.1
                         ; set RDEN bit, enable read operations
SET IAR1.0
                         ; start Read Cycle - set RD bit
BACK:
SZ IAR1.0
                        ; check for read cycle end
JMP BACK
                         ; disable EEPROM read/write
CLR IAR1
CLR MP1H
MOV A, EED
                         ; move read data to register
MOV READ DATA, A
```

### Writing Data to the EEPROM - polling method

```
MOV A, EEPROM ADRES
                         ; user defined address
MOV EEA, A
MOV A, EEPROM DATA
                         ; user defined data
MOV EED, A
MOV A, 040H
                         ; setup memory pointer MP1L
                         ; MP1 points to EEC register
MOV MP1L, A
MOV A, 01H
                         ; setup memory pointer MP1H

CLR EMI
SET IAR1.3
                          ; set WREN bit, enable write operations
SET IAR1.2
                          ; start Write Cycle - set WR bit - executed immediately
                          ; after set WREN bit
SET EMI
BACK:
                         ; check for write cycle end
SZ IAR1.2
JMP BACK
CLR IAR1
                         ; disable EEPROM read/write
CLR MP1H
```

## **Oscillators**

Various oscillator options offer the user a wide range of functions according to their various application requirements. The flexible features of the oscillator functions ensure that the best optimisation can be achieved in terms of speed and power saving. Oscillator selections and operation are selected through registers.

#### **Oscillator Overview**

In addition to being the source of the main system clock the oscillators also provide clock sources for the Watchdog Timer and Time Base Interrupts. Fully integrated internal oscillators, requiring no external components, are provided to form a wide range of both fast and slow system oscillators. The higher frequency oscillators provide higher performance but carry with it the disadvantage of higher power requirements, while the opposite is of course true for the lower frequency oscillators. With the capability of dynamically switching between fast and slow system clock, the device has the flexibility to optimize the performance/power ratio, a feature especially important in power sensitive portable applications.

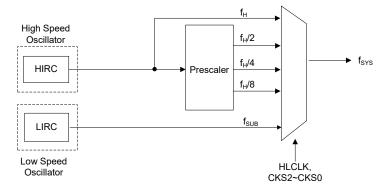

| Туре                   | Name | Freq. |
|------------------------|------|-------|
| Internal High Speed RC | HIRC | 8MHz  |
| Internal Low Speed RC  | LIRC | 32kHz |

**Oscillator Types** 

### **System Clock Configurations**

There are two methods of generating the system clock, one high speed oscillator and one low speed oscillator. The high speed oscillator is the internal 8MHz RC oscillator. The low speed oscillator is the internal 32kHz RC oscillator. Selecting whether the low or high speed oscillator is used as the system oscillator is implemented using the HLCLK and CKS2~CKS0 bits in the SMOD register and as the system clock can be dynamically selected.

The frequency of the slow speed or high speed system clock is also determined using HLCLK and CKS2~CKS0 bits in the SMOD register. Note that two oscillator selections must be made namely one high speed and one low speed system oscillators. It is not possible to choose a no-oscillator selection for either the high or low speed oscillator.

**System Clock Configurations** 

Rev. 1.50 40 October 26, 2023

#### Internal RC Oscillator - HIRC

The internal RC oscillator is a fully integrated system oscillator requiring no external components. The internal RC oscillator has a fixed frequency of 8MHz. Device trimming during the manufacturing process and the inclusion of internal frequency compensation circuits are used to ensure that the influence of the power supply voltage, temperature and process variations on the oscillation frequency are minimised. It requires no external pins for its operation.

### Internal 32kHz Oscillator - LIRC

The internal 32kHz System Oscillator is the low frequency oscillator. It is a fully integrated RC oscillator with a typical frequency of 32kHz at 5V, requiring no external components for its implementation. Device trimming during the manufacturing process and the inclusion of internal frequency compensation circuits are used to ensure that the influence of the power supply voltage, temperature and process variations on the oscillation frequency are minimised.

# **Operating Modes and System Clocks**

Present day applications require that their microcontrollers have high performance but often still demand that they consume as little power as possible, conflicting requirements that are especially true in battery powered portable applications. The fast clocks required for high performance will by their nature increase current consumption and of course vice-versa, lower speed clocks reduce current consumption. As Holtek has provided these devices with both high and low speed clock sources and the means to switch between them dynamically, the user can optimise the operation of their microcontroller to achieve the best performance/power ratio.

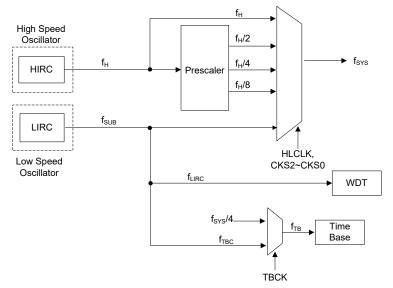

### **System Clocks**

The devices have many different clock sources for both the CPU and peripheral function operation. By providing the user with a wide range of clock options using register programming, a clock system can be configured to obtain maximum application performance.

The main system clock, can come from either a high frequency  $f_H$  or low frequency  $f_{SUB}$  source, and is selected using the HLCLK bit and CKS2~CKS0 bits in the SMOD register. The high speed system clock can be sourced from the HIRC oscillator. The low speed system clock source can be sourced from the LIRC oscillator. The other choice, which is a divided version of the high speed system oscillator has a range of  $f_H/2\sim f_H/8$ .

Rev. 1.50 41 October 26, 2023

**Device Clock Configurations** 

Note: When the system clock source  $f_{SYS}$  is switched to  $f_{SUB}$  from  $f_H$ , the high speed oscillation will stop to conserve the power. Thus there are also no the divided frequencies of  $f_H$  for peripheral circuit to use.

## **System Operation Modes**

There are five different modes of operation for the microcontroller, each one with its own special characteristics and which can be chosen according to the specific performance and power requirements of the application. There are two modes allowing normal operation of the microcontroller, the NORMAL Mode and SLOW Mode. The remaining three modes, the SLEEP, IDLE0 and IDLE1 Mode are used when the microcontroller CPU is switched off to conserve power.

| Operating Mode |     | Descr                             | iption            |                         |
|----------------|-----|-----------------------------------|-------------------|-------------------------|
| Operating Mode | CPU | fsys                              | f <sub>LIRC</sub> | <b>f</b> <sub>TBC</sub> |
| NORMAL Mode    | On  | f <sub>H</sub> ~f <sub>H</sub> /8 | On                | On                      |
| SLOW Mode      | On  | f <sub>SUB</sub>                  | On                | On                      |
| IDLE0 Mode     | Off | Off                               | On                | On                      |
| IDLE1 Mode     | Off | On                                | On                | On                      |
| SLEEP Mode     | Off | Off                               | On                | Off                     |

### **NORMAL Mode**

As the name suggests this is one of the main operating modes where the microcontroller has all of its functions operational and where the system clock is provided by the high speed oscillator. This mode operates allowing the microcontroller to operate normally with a clock source will come from the high speed oscillator HIRC. The high speed oscillator will however first be divided by a ratio ranging from 1 to 8, the actual ratio being selected by the CKS2~CKS0 and HLCLK bits in the SMOD register. Although a high speed oscillator is used, running the microcontroller at a divided clock ratio reduces the operating current.

Rev. 1.50 42 October 26, 2023

#### **SLOW Mode**

This is also a mode where the microcontroller operates normally although now with a slower speed clock source. The clock source used will be from  $f_{SUB}$ . The  $f_{SUB}$  clock is derived from the LIRC oscillator. Running the microcontroller in this mode allows it to run with much lower operating currents. In the SLOW Mode, the  $f_H$  is off.

#### **SLEEP Mode**

The SLEEP Mode is entered when an HALT instruction is executed and when the IDLEN bit in the SMOD register is low. In the SLEEP mode the CPU will be stopped. However the fLIRC clock will continue to operate to keep the Watchdog Timer function.

#### **IDLE0 Mode**

The IDLE0 Mode is entered when a HALT instruction is executed and when the IDLEN bit in the SMOD register is high and the FSYSON bit in the CTRL register is low. In the IDLE0 Mode the system oscillator will be inhibited from driving the CPU and the system oscillator will be stopped, but the low speed oscillator will be on.

### **IDLE1 Mode**

The IDLE1 Mode is entered when a HALT instruction is executed and when the IDLEN bit in the SMOD register is high and the FSYSON bit in the CTRL register is high. In the IDLE1 Mode the system oscillator will be inhibited from driving the CPU, the system oscillator will continue to run, and this system oscillator may be high speed or low speed system oscillator. In the IDLE1 Mode the low frequency clock will be on.

Note: If LVDEN=1 and the SLEEP or IDLE mode is entered, the LVD and bandgap functions will not be disabled, and the f<sub>SUB</sub> clock will be forced to open.

### **Control Register**

The registers, SMOD and CTRL, are used to control the system clock and the corresponding oscillator configurations.

### SMOD Register

| Bit  | 7    | 6    | 5    | 4 | 3   | 2   | 1     | 0     |
|------|------|------|------|---|-----|-----|-------|-------|
| Name | CKS2 | CKS1 | CKS0 | _ | LTO | НТО | IDLEN | HLCLK |
| R/W  | R/W  | R/W  | R/W  | _ | R   | R   | R/W   | R/W   |
| POR  | 0    | 0    | 0    | _ | 0   | 0   | 1     | 1     |

Bit 7~5 CKS2~CKS0: System clock selection

000:  $f_{SUB}$ 001:  $f_{SUB}$ 010: Undefined 011: Undefined 100: Undefined 101:  $f_{H}/8$ 

110: f<sub>H</sub>/4 111: f<sub>H</sub>/2

These three bits are used to select which clock is used as the system clock source. In addition to the system clock source directly derived from  $f_H$  or  $f_{SUB}$ , a divided version of the high speed system oscillator can also be chosen as the system clock source.

Bit 4 Unimplemented, read as "0"

Bit 3 LTO: LIRC System OSC SST ready flag

0: Not ready 1: Ready

This is the low speed system oscillator SST ready flag which indicates when the low speed system oscillator is stable after power on reset or a wake-up has occurred. The flag will change to a high level after  $1\sim2$  cycles.

Bit 2 HTO: HIRC System OSC SST ready flag

0: Not ready 1: Ready

This is the high speed system oscillator SST ready flag which indicates when the high speed system oscillator is stable after a wake-up has occurred. The flag will change to a high level after 15~16 clock cycles if the HIRC oscillator is used.

Bit 1 IDLEN: IDLE Mode Control

0: Disable 1: Enable

This is the IDLE Mode Control bit and determines what happens when the HALT instruction is executed. If this bit is high, when a HALT instruction is executed the device will enter the IDLE Mode. In the IDLE1 Mode the CPU will stop running but the system clock will continue to keep the peripheral functions operational, if FSYSON bit is high. If FSYSON bit is low, the CPU and the system clock will all stop in IDLE0 mode. If the bit is low the device will enter the SLEEP Mode when a HALT instruction is executed.

Bit 0 HLCLK: System Clock Selection

0:  $f_H/2 \sim f_H/8$  or  $f_{SUB}$ 

1: f<sub>H</sub>

This bit is used to select if the  $f_H$  clock or the  $f_H/2 \sim f_H/8$  or  $f_{SUB}$  clock is used as the system clock. When the bit is high the  $f_H$  clock will be selected and if low the  $f_H/2 \sim f_H/8$  or  $f_{SUB}$  clock will be selected. When system clock switches from the  $f_H$  clock to the  $f_{SUB}$  clock and the  $f_H$  clock will be automatically switched off to conserve power.

### **Operating Mode Switching**

The device can switch between operating modes dynamically allowing the user to select the best performance/power ratio for the present task in hand. In this way microcontroller operations that do not require high performance can be executed using slower clocks thus requiring less operating current and prolonging battery life in portable applications.

In simple terms, Mode Switching between the NORMAL Mode and SLOW Mode is executed using the HLCLK bit and CKS2~CKS0 bits in the SMOD register while Mode Switching from the NORMAL/SLOW Modes to the SLEEP/IDLE Modes is executed via the HALT instruction. When a HALT instruction is executed, whether the device enters the IDLE0 Mode, IDLE1 Mode or the SLEEP Mode is determined by the condition of the IDLEN bit in the SMOD register and FSYSON in the CTRL register.

When the HLCLK bit switches to a low level, which implies that clock source is switched from the high speed clock source,  $f_H$ , to the clock source,  $f_H/2\sim f_H/8$  or  $f_{SUB}$ . If the clock is from the  $f_{SUB}$ , the high speed clock source will stop running to conserve power. When this happens it must be noted that the  $f_H/16$  and  $f_H/64$  internal clock sources will also stop running, which may affect the operation of other internal functions such as the TMs. The accompanying flowchart shows what happens when the device moves between the various operating modes.

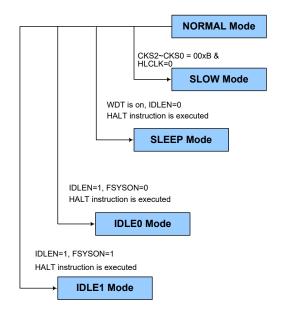

### **NORMAL Mode to SLOW Mode Switching**

When running in the NORMAL Mode, which uses the high speed system oscillator, and therefore consumes more power, the system clock can switch to run in the SLOW Mode by setting the HLCLK bit to "0" and setting the CKS2~CKS0 bits to "000" or "001" in the SMOD register. This will then use the low speed system oscillator which will consume less power. Users may decide to do this for certain operations which do not require high performance and can subsequently reduce power consumption.

The SLOW Mode is sourced from the LIRC oscillator and therefore requires this oscillator to be stable before full mode switching occurs. This is monitored using the LTO bit in the SMOD register.

Rev. 1.50 45 October 26, 2023

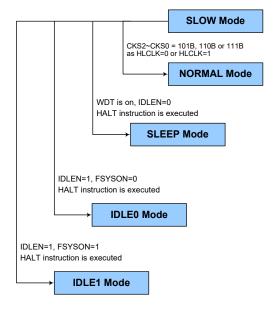

### **SLOW Mode to NORMAL Mode Switching**

In SLOW Mode the system uses LIRC low speed system oscillator. To switch back to the NORMAL Mode, where the high speed system oscillator is used, the HLCLK bit should be set to "1" or HLCLK bit is "0", but CKS2~CKS0 is set to "101", "110" or "111".

As a certain amount of time will be required for the high frequency clock to stabilise, the status of the HTO bit is checked. The time duration required for the high speed system oscillator stabilization is specified in the A.C. characteristics.

Rev. 1.50 46 October 26, 2023

### **Entering the SLEEP Mode**

There is only one way for the device to enter the SLEEP Mode and that is to execute the "HALT" instruction in the application program with the IDLEN bit in SMOD register equal to "0" and the WDT or LVD on. When this instruction is executed under the conditions described above, the following will occur:

- The system clock and Time Base clock will be stopped and the application program will stop at the "HALT" instruction, but the WDT and LVD will remain on with the clock source coming from the  $f_{LIRC}$  clock.
- The Data Memory contents and registers will maintain their present condition.
- The WDT will be cleared and resume counting.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag PDF will be set, and WDT timeout flag TO will be cleared.

#### **Entering the IDLE0 Mode**

There is only one way for the device to enter the IDLE0 Mode and that is to execute the "HALT" instruction in the application program with the IDLEN bit in SMOD register equal to "1" and the FSYSON bit in CTRL register equal to "0". When this instruction is executed under the conditions described above, the following will occur:

- The system clock will be stopped and the application program will stop at the "HALT" instruction, but the Time Base clock and the  $f_{LIRC}$  clock will be on.
- The Data Memory contents and registers will maintain their present condition.
- The WDT will be cleared and resume counting.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag PDF will be set, and WDT timeout flag TO will be cleared.

#### **Entering the IDLE1 Mode**

There is only one way for the device to enter the IDLE1 Mode and that is to execute the "HALT" instruction in the application program with the IDLEN bit in SMOD register equal to "1" and the FSYSON bit in CTRL register equal to "1". When this instruction is executed under the conditions described above, the following will occur:

- The system clock, Time Base clock and the  $f_{LIRC}$  clock will be on and the application program will stop at the "HALT" instruction.
- The Data Memory contents and registers will maintain their present condition.
- The WDT will be cleared and resume counting.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag PDF will be set, and WDT timeout flag TO will be cleared.

Rev. 1.50 47 October 26, 2023

### **Standby Current Considerations**

As the main reason for entering the SLEEP or IDLE Mode is to keep the current consumption of the device to as low a value as possible, perhaps only in the order of several micro-amps except in the IDLE1 Mode, there are other considerations which must also be taken into account by the circuit designer if the power consumption is to be minimised. Special attention must be made to the I/O pins on the device. All high-impedance input pins must be connected to either a fixed high or low level as any floating input pins could create internal oscillations and result in increased current consumption. This also applies to the device which has different package types, as there may be unbonded pins. These must either be setup as outputs or if setup as inputs must have pull-high resistors connected.

Care must also be taken with the loads, which are connected to I/O pins, which are setup as outputs. These should be placed in a condition in which minimum current is drawn or connected only to external circuits that do not draw current, such as other CMOS inputs. Also note that additional standby current will also be required if the LIRC oscillator has enabled.

#### Wake-up

After the system enters the SLEEP or IDLE Mode, it can be woken up from one of various sources listed as follows:

- · An external falling edge on Port A
- · A system interrupt
- · A WDT overflow

When the device executes the "HALT" instruction, the PDF flag will be set to 1. The PDF flag will be cleared to 0 if the device experiences a system power-up or executes the clear Watchdog Timer instruction. If the system is woken up by a WDT overflow, a Watchdog Timer reset will be initiated and the TO flag will be set to 1. The TO flag is set if a WDT time-out occurs and causes a wake-up that only resets the Program Counter and Stack Pointer, other flags remain in their original status.

Each pin on Port A can be setup using the PAWU register to permit a negative transition on the pin to wake-up the system. When a Port A pin wake-up occurs, the program will resume execution at the instruction following the "HALT" instruction. If the system is woken up by an interrupt, then two possible situations may occur. The first is where the related interrupt is disabled or the interrupt is enabled but the stack is full, in which case the program will resume execution at the instruction following the "HALT" instruction. In this situation, the interrupt which woke-up the device will not be immediately serviced, but will rather be serviced later when the related interrupt is finally enabled or when a stack level becomes free. The other situation is where the related interrupt is enabled and the stack is not full, in which case the regular interrupt response takes place. If an interrupt request flag is set high before entering the SLEEP or IDLE Mode, the wake-up function of the related interrupt will be disabled.

Rev. 1.50 48 October 26, 2023

# **Watchdog Timer**

The Watchdog Timer is provided to prevent program malfunctions or sequences from jumping to unknown locations, due to certain uncontrollable external events such as electrical noise.

## **Watchdog Timer Clock Source**

The Watchdog Timer clock source is provided by the internal clock, fLIRC, which is in turn supplied by the LIRC oscillator. The Watchdog Timer source clock is then subdivided by a ratio of 28 to 218 to give longer timeouts, the actual value being chosen using the WS2~WS0 bits in the WDTC register. The LIRC internal oscillator has an approximate frequency of 32kHz and this specified internal clock period can vary with V<sub>DD</sub>, temperature and process variations.

## **Watchdog Timer Control Register**

A single register, WDTC, controls the required timeout period as well as the enable and MCU software reset operation.

### WDTC Register

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | WE4 | WE3 | WE2 | WE1 | WE0 | WS2 | WS1 | WS0 |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | 0   | 1   | 0   | 1   | 0   | 0   | 1   | 1   |

Bit 7~3 WE4~WE0: WDT function software control

> 01010B or 10101B: Enabled Other values: Reset MCU

When these bits are changed due to adverse environmental conditions, the microcontroller will be reset. The reset operation will be activated after t<sub>SRESET</sub> time and the WRF bit in the CTRL register will be set high.

WS2~WS0: WDT time-out period selection Bit 2~0

 $000: 2^8/f_{LIRC}$  $001: 2^{10}/f_{LIRC}$  $010: 2^{12}/f_{LIRC}$ 011:  $2^{14}/f_{LIRC}$  $100: 2^{15}/f_{LIRC}$  $101: 2^{16}/f_{LIRC}$ 

110:  $2^{17}/f_{LIRC}$  $111: 2^{18}/f_{LIRC}$ 

These three bits determine the division ratio of the watchdog timer source clock, which in turn determines the time-out period.

#### CTRL Register

| Bit  | 7      | 6 | 5 | 4 | 3 | 2    | 1   | 0   |
|------|--------|---|---|---|---|------|-----|-----|
| Name | FSYSON | _ | _ | _ | _ | LVRF | LRF | WRF |
| R/W  | R/W    | _ | _ | _ | _ | R/W  | R/W | R/W |
| POR  | 0      | _ | _ | _ | _ | х    | 0   | 0   |

"x" unknown

Bit 7 FSYSON: System clock f<sub>SYS</sub> Control in IDLE Mode

Described elsewhere.

Bit 6~3 Unimplemented, read as "0" Bit 2 LVRF: LVR function reset flag

Described elsewhere.

Bit 1 LRF: LVRC Control register software reset flag

Described elsewhere.

Bit 0 WRF: WDTC Control register software reset flag

0: Not occur 1: Occurred

This bit is set high by the WDT Control register software reset and cleared by the application program. Note that this bit can only be cleared to zero by the application program.

## **Watchdog Timer Operation**

The Watchdog Timer operates by providing a device reset when its timer overflows. This means that in the application program and during normal operation the user has to strategically clear the Watchdog Timer before it overflows to prevent the Watchdog Timer from executing a reset. This is done using the clear watchdog instructions. If the program malfunctions for whatever reason, jumps to an unknown location, or enters an endless loop, the clear WDT instruction will not be executed in the correct manner, in which case the Watchdog Timer will overflow and reset the device.

There are five bits, WE4~WE0, in the WDTC register to enable the WDT function. When the WE4~WE0 bits value is equal to 01010B or 10101B, the WDT function is enabled. However, if the WE4~WE0 bits are changed to any other values except 01010B and 10101B, which could be caused by adverse environmental conditions such as noise, it will reset the microcontroller after t<sub>SRESET</sub> time. After power on these bits will have a value of 01010B.

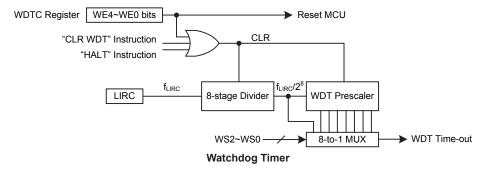

| WE4 ~ WE0 Bits   | WDT Function |
|------------------|--------------|
| 01010B / 10101B  | Enable       |
| Any other values | Reset MCU    |

**Watchdog Timer Function Control** 

Under normal program operation, a Watchdog Timer time-out will initialise a device reset and set the status bit TO. However, if the system is in the SLEEP or IDLE Mode, when a Watchdog Timer time-out occurs, the TO and PDF bits in the status register will be set and only the Program Counter and Stack Pointer will be reset. Three methods can be adopted to clear the contents of the Watchdog Timer. The first is a WDT reset, which means a certain value except 01010B and 10101B written into the WE4~WE0 bit filed, the second is using the Watchdog Timer software clear instruction and the third is via a HALT instruction.

There is only one method of using software instruction to clear the Watchdog Timer. That is to use the single "CLR WDT" instruction to clear the WDT.

The maximum time out period is when the  $2^{18}$  division ratio is selected. As an example, with a 32kHz LIRC oscillator as its source clock, this will give a maximum watchdog period of around 8 second for the  $2^{18}$  division ratio, and a minimum timeout of 8ms for the  $2^{8}$  division ration.

## Reset and Initialisation

A reset function is a fundamental part of any microcontroller ensuring that the device can be set to some predetermined condition irrespective of outside parameters. The most important reset condition is after power is first applied to the microcontroller. In this case, internal circuitry will ensure that the microcontroller, after a short delay, will be in a well-defined state and ready to execute the first program instruction. After this power-on reset, certain important internal registers will be set to defined states before the program commences. One of these registers is the Program Counter, which will be reset to zero forcing the microcontroller to begin program execution from the lowest Program Memory address.

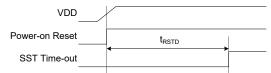

Another type of reset is when the Watchdog Timer overflows and resets. All types of reset operations result in different register conditions being setup. Another reset exists in the form of a Low Voltage Reset, LVR, where a full reset, is implemented in situations where the power supply voltage falls below a certain threshold.

#### **Reset Functions**

There are several ways in which a microcontroller reset can occur, through events occurring internally.

#### **Power-on Reset**

The most fundamental and unavoidable reset is the one that occurs after power is first applied to the microcontroller. As well as ensuring that the Program Memory begins execution from the first memory address, a power-on reset also ensures that certain other registers are preset to known conditions. All the I/O port and port control registers will power up in a high condition ensuring that all I/O ports will be first set to inputs.

Note:  $t_{RSTD}$  is power-on delay, typical time=16.7ms **Power-On Reset Timing Chart** 

### Low Voltage Reset - LVR

The microcontroller contains a low voltage reset circuit in order to monitor the supply voltage of the device. The LVR function is always enabled with a specific LVR voltage,  $V_{LVR}$ . If the supply voltage of the device drops to within a range of  $0.9V\sim V_{LVR}$  such as might occur when changing the battery, the LVR will automatically reset the device internally and the LVRF bit in the CTRL register will also be set high. For a valid LVR signal, a low voltage, i.e., a voltage in the range between  $0.9V\sim V_{LVR}$  must exist for greater than the value  $t_{LVR}$  specified in the LVD/LVR Electrical Characteristics. If the low voltage state does not exceed this value, the LVR will ignore the low supply voltage and will not perform a reset function.

The actual  $V_{\text{LVR}}$  value is fixed at a value of 2.55V. However the LVS7~LVS0 bits still have effects on the LVR function. If these bits are changed to any other value except some certain values defined in the LVRC register by the environmental noise, the LVR will reset the device after  $t_{\text{SRESET}}$  time. When this happens, the LRF bit in the CTRL register will be set high. After power on the register will have the value of 01010101B. Note that the LVR function will be automatically disabled when the device enters the power down mode.

Rev. 1.50 51 October 26, 2023

Note:  $t_{RSTD}$  is power-on delay, typical time=16.7ms

### **Low Voltage Reset Timing Chart**

### LVRC Register

| Bit  | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|
| Name | LVS7 | LVS6 | LVS5 | LVS4 | LVS3 | LVS2 | LVS1 | LVS0 |
| R/W  |
| POR  | 0    | 1    | 0    | 1    | 0    | 1    | 0    | 1    |

Bit 7~0 LVS7~LVS0: LVR voltage select

01010101: 2.55V 00110011: 2.55V 10011001: 2.55V 10101010: 2.55V

Other values: MCU reset (register is reset to POR value).

When an actual low voltage condition occurs, an MCU reset will be generated. In this situation this register contents will remain the same after such a reset occurs.

Any register value, other than the defined value above, will also result in the generation of an MCU reset. The reset operation will be activated after  $t_{SRESET}$  time. However in this situation this register contents will be reset to the POR value.

### CTRL Register

| Bit  | 7      | 6 | 5 | 4 | 3 | 2    | 1   | 0   |
|------|--------|---|---|---|---|------|-----|-----|
| Name | FSYSON | _ | _ | _ | _ | LVRF | LRF | WRF |
| R/W  | R/W    | _ | _ | _ | _ | R/W  | R/W | R/W |
| POR  | 0      | _ | _ | _ | _ | Х    | 0   | 0   |

"x" unknown

Bit 7 **FSYSON**: System clock f<sub>SYS</sub> Control in IDLE Mode

Described elsewhere.

Bit 6~3 Unimplemented, read as "0"

Bit 2 LVRF: LVR function reset flag

0: Not occur 1: Occurred

This bit is set high when a specific Low Voltage Reset situation condition occurs. This bit can only be cleared to zero by the application program.

Bit 1 LRF: LVRC Control register software reset flag

0: Not occur
1: Occurred

This bit is set high if the LVRC register contains any non-defined LVR voltage register values. This in effect acts like a software-reset function. This bit can only be cleared to zero by the application program.

Bit 0 WRF: WDTC Control register software reset flag

Described elsewhere.

Rev. 1.50 52 October 26, 2023

### **Watchdog Time-out Reset during Normal Operation**

The Watchdog time-out Reset during normal operation is the same as LVR reset except that the Watchdog time-out flag TO will be set high.

Note: t<sub>RSTD</sub> is power-on delay, typical time=16.7ms

WDT Time-out Reset during Normal Operation Timing Chart

### Watchdog Time-out Reset during SLEEP or IDLE Mode

The Watchdog time-out Reset during SLEEP or IDLE Mode is a little different from other kinds of reset. Most of the conditions remain unchanged except that the Program Counter and the Stack Pointer will be cleared to zero and the TO and PDF flags will be set high. Refer to the A.C. Characteristics for t<sub>SST</sub> details.

WDT Time-out Reset during Sleep or IDLE Mode Timing Chart

### **Reset Initial Conditions**

The different types of reset described affect the reset flags in different ways. These flags, known as PDF and TO are located in the status register and are controlled by various microcontroller operations, such as the SLEEP or IDLE Mode function or Watchdog Timer. The reset flags are shown in the table:

| то | PDF | Reset Conditions  |
|----|-----|---|
| 0  | 0   | Power-on reset  |
| u  | u   | LVR reset during Normal or SLOW Mode operation          |
| 1  | u   | WDT time-out reset during Normal or SLOW Mode operation |
| 1  | 1   | WDT time-out reset during IDLE or SLEEP Mode operation  |

Note: "u" stands for unchanged

The following table indicates the way in which the various components of the microcontroller are affected after a power-on reset occurs.

| Item               | Conditions after Reset                           |  |  |  |  |
|--------------------|--|--|--|--|--|
| Program Counter    | Reset to zero                                    |  |  |  |  |
| Interrupts         | All interrupts will be disabled                  |  |  |  |  |
| WDT                | Clear after reset, WDT begins counting           |  |  |  |  |
| Timer Modules      | Timer Modules will be turned off                 |  |  |  |  |
| Input/Output Ports | I/O ports will be setup as inputs                |  |  |  |  |
| Stack Pointer      | Stack Pointer will point to the top of the stack |  |  |  |  |

Rev. 1.50 53 October 26, 2023

The different kinds of resets all affect the internal registers of the microcontroller in different ways. To ensure reliable continuation of normal program execution after a reset occurs, it is important to know what condition the microcontroller is in after a particular reset occurs. The following table describes how each type of reset affects each of the microcontroller internal registers.

| IRRO   | Register        | Power On Reset | WDT Time-out                                     | WDT Time-out |

# **Input / Output Ports**

Holtek microcontrollers offer considerable flexibility on their I/O ports. With the input or output designation of every pin fully under user program control, pull-high selections for all ports and wake-up selections on certain pins, the user is provided with an I/O structure to meet the needs of a wide range of application possibilities.

The device provides bidirectional input/output lines labeled with port names PA~PD. These I/O ports are mapped to the RAM Data Memory with specific addresses as shown in the Special Purpose Data Memory table. All of these I/O ports can be used for input and output operations. For input operation, these ports are non-latching, which means the inputs must be ready at the T2 rising edge of instruction "MOV A, [m]", where m denotes the port address. For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

I/O Basic Function Register List

### **Pull-high Resistors**

Many product applications require pull-high resistors for their switch inputs usually requiring the use of an external resistor. To eliminate the need for these external resistors, all I/O pins, when configured as an input have the capability of being connected to an internal pull-high resistor. These pull-high resistors are selected using registers PAPU~PDPU, and are implemented using weak PMOS transistors.

Note that the pull-high resistor can be controlled by the relevant pull-high control register only when the pin-shared functional pin is selected as a digital input or NMOS output. Otherwise, the pull-high resistors cannot be enabled.

Rev. 1.50 57 October 26, 2023

#### PxPU Register

| Bit  | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|------|-------|-------|-------|-------|-------|-------|-------|-------|
| Name | PxPU7 | PxPU6 | PxPU5 | PxPU4 | PxPU3 | PxPU2 | PxPU1 | PxPU0 |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |
| POR  | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |

PxPUn: I/O Port x Pin pull-high function control

0: Disable 1: Enable

The PxPUn bit is used to control the pin pull-high function. Here the "x" can be A, B C or D. However, the actual available bits for each I/O Port may be different.

For the HT45F5N, PA4 PA5, PD6 and PD7 are not bounded to the external package, the PAPU and PDPU registers must be fixed at "0" after power on.

### Port A Wake-up

The HALT instruction forces the microcontroller into the SLEEP or IDLE Mode which preserves power, a feature that is important for battery and other low-power applications. Various methods exist to wake-up the microcontroller, one of which is to change the logic condition on one of the Port A pins from high to low. This function is especially suitable for applications that can be woken up via external switches. Each pin on Port A can be selected individually to have this wake-up feature using the PAWU register.

Note that the wake-up function can be controlled by the wake-up control register only when the pinshared functional pin is selected as general purpose input/output and the MCU enters the Power down mode.

### PAWU Register

| Bit  | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|------|-------|-------|-------|-------|-------|-------|-------|-------|
| Name | PAWU7 | PAWU6 | PAWU5 | PAWU4 | PAWU3 | PAWU2 | PAWU1 | PAWU0 |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |
| POR  | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |

Bit 7~0 PAWU7~PAWU0: Port A Pin Wake-up Control

0: Disable 1: Enable

For the HT45F5N, PA4 and PA5 are not bounded to the external package.

### I/O Port Control Registers

Each I/O port has its own control register known as PAC~PDC, to control the input/output configuration. With this control register, each CMOS output or input can be reconfigured dynamically under software control. Each pin of the I/O ports is directly mapped to a bit in its associated port control register. For the I/O pin to function as an input, the corresponding bit of the control register must be written as a "1". This will then allow the logic state of the input pin to be directly read by instructions. When the corresponding bit of the control register is written as a "0", the I/O pin will be setup as a CMOS output. If the pin is currently setup as an output, instructions can still be used to read the output register. However, it should be noted that the program will in fact only read the status of the output data latch and not the actual logic status of the output pin.

### PxC Register

| Bit  | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|
| Name | PxC7 | PxC6 | PxC5 | PxC4 | PxC3 | PxC2 | PxC1 | PxC0 |
| R/W  |
| POR  | 1    | 1    | 1    | 1    | 1    | 1    | 1    | 1    |

PxCn: I/O Port x Pin type selection

0: Output

1: Input

The PxCn bit is used to control the pin type selection. Here the "x" can be A, B, C or D. However, the actual available bits for each I/O Port may be different.

For the HT45F5N, PA4, PA5, PD6 and PD7 are not bounded to the external package, the PAC and PDC registers must be cleared to "0" after power on to set the corresponding pins as an output.

### **Slew Rate Control**

The PB0~PB3 ports can be setup to have a choice of various slew rate using the SLEWC0 and SLEWC1 registers.

Refer to the Slew Rate Control Characteristics section to obtain the exact value for different applications.

| Register |             | Bit |   |   |         |         |         |         |  |  |  |
|----------|-------------|-----|---|---|---------|---------|---------|---------|--|--|--|
| Name     | 7 6 5 4 3 2 |     |   |   |         |         | 1       | 0       |  |  |  |

| R/W  | _ | _ | _ | _ | R/W     | R/W     | R/W     | R/W     |
| POR  | _ | _ | _ | _ | 0       | 0       | 0       | 0       |

Bit 7~6 Unimplemented, read as "0"

Bit 3~2 SLEWC13~SLEWC12: PB3 output slew rate selection

00: Slew rate=Level 0 01: Slew rate=Level 1 10: Slew rate=Level 2 11: Slew rate=Level 3

Bit 1~0 SLEWC11~SLEWC10: PB1 output slew rate selection

00: Slew rate=Level 0 01: Slew rate=Level 1 10: Slew rate=Level 2 11: Slew rate=Level 3

Note: Users should refer to the Slew Rate Control Characteristics section to obtain the exact value for different applications.

#### **Pin-shared Function**

The flexibility of the microcontroller range is greatly enhanced by the use of pins that have more than one function. Limited numbers of pins can force serious design constraints on designers but by supplying pins with multi-functions, many of these difficulties can be overcome. For these pins, the desired function of the multi-function I/O pins is selected by a series of registers via the application program control.

#### **Pin-shared Function Selection Registers**

The limited number of supplied pins in a package can impose restrictions on the amount of functions a certain device can contain. However by allowing the same pin to share several different functions and providing a means of function selection, a wide range of different functions can be incorporated into even relatively small package sizes. The device includes Port "x" output function selection register "n", labeled as PxPSn, and some pin function selection register, PRM, which can select the desired functions of the multi-function pin-shared pins

The most important point to note is to make sure that the desired pin-shared function is properly selected and also deselected. To select the desired pin-shared function, the pin-shared function should first be correctly selected using the corresponding pin-shared control register. After that the corresponding peripheral functional setting should be configured and then the peripheral function can be enabled. To correctly deselect the pin-shared function, the peripheral function should first be disabled and then the corresponding pin-shared function control register can be modified to select other pin-shared functions.

| Register |       |       |        |        | Bit   |         |           |        |

For the HT45F5N, PA4, PA5, PD6 and PD7 are not bounded to the external package, SDIPRM and SDOPRM bits must be fixed at "00" after power on.

#### I/O Pin Structures

The accompanying diagrams illustrate the internal structures of some generic I/O pin types. As the exact logical construction of the I/O pin will differ from these drawings, they are supplied as a guide only to assist with the functional understanding of the I/O pins. The wide range of pin-shared structures does not permit all types to be shown.

**Generic Input/Output Structure** 

A/D Input/Output Structure

### **Programming Considerations**

Within the user program, one of the first things to consider is port initialisation. After a reset, all of the I/O data and port control registers will be set high. This means that all I/O pins will default to an input state, the level of which depends on the other connected circuitry and whether pull-high selections have been chosen. If the port control registers, PAC~PDC, are then programmed to setup some pins as outputs, these output pins will have an initial high output value unless the associated port data registers, PA~PD, are first programmed. Selecting which pins are inputs and which are outputs can be achieved byte-wide by loading the correct values into the appropriate port control register or by programming individual bits in the port control register using the "SET [m].i" and "CLR [m].i" instructions. Note that when using these bit control instructions, a read-modify-write operation takes place. The microcontroller must first read in the data on the entire port, modify it to the required new bit values and then rewrite this data back to the output ports.

Port A has the additional capability of providing wake-up functions. When the device is in the SLEEP or IDLE Mode, various methods are available to wake the device up. One of these is a high to low transition of any of the Port A pins. Single or multiple pins on Port A can be setup to have this function.

### **Timer Modules - TM**

One of the most fundamental functions in any microcontroller device is the ability to control and measure time. To implement time related functions the device includes several Timer Modules, abbreviated to the name TM. The TMs are multi-purpose timing units and serve to provide operations such as Timer/Counter, Input Capture, Compare Match Output and Single Pulse Output as well as being the functional unit for the generation of PWM signals. Each of the TMs has two individual interrupts. The addition of input and output pins for each TM ensures that users are provided with timing units with a wide and flexible range of features.

The common features of the different TM types are described here with more detailed information provided in the individual Standard and Periodic TM section.

#### Introduction

The devices contain a 16-bit Standard TM and a 10-bit Periodic TM, having a reference name of STM and PTM. Although similar in nature, the different TM types vary in their feature complexity. The common features to the Standard and Periodic TMs will be described in this section and the detailed operation will be described in corresponding sections. The main features and differences between the two types of TMs are summarised in the accompanying table.

| Function                     | STM            | PTM            |  |  |
|------------------------------|----------------|----------------|--|--|
| Timer/Counter                | V              | $\sqrt{}$      |  |  |
| I/P Capture                  | V              | V              |  |  |
| Compare Match Output         | V              | $\sqrt{}$      |  |  |
| PWM Channels                 | 1              | 1              |  |  |
| Single Pulse Output          | 1              | 1              |  |  |

**TM Function Summary** 

Rev. 1.50 66 October 26, 2023

### **TM Operation**

The two different types of TMs offer a diverse range of functions, from simple timing operations to PWM signal generation. The key to understanding how the TM operates is to see it in terms of a free running counter whose value is then compared with the value of pre-programmed internal comparators. When the free running counter has the same value as the pre-programmed comparator, known as a compare match situation, a TM interrupt signal will be generated which can clear the counter and perhaps also change the condition of the TM output pin. The internal TM counter is driven by a user selectable clock source, which can be an internal clock or an external pin.

#### **TM Clock Source**

The clock source which drives the main counter in each TM can originate from various sources. The selection of the required clock source is implemented using the  $xTCK2\sim xTCK0$  bits in the xTM control registers, where "x" stands for S or P type TM. The clock source can be a ratio of either the system clock  $f_{SYS}$  or the internal high clock  $f_{H}$ , the  $f_{TBC}$  clock source or the external xTCK pin. The xTCK pin clock source is used to allow an external signal to drive the TM as an external clock source or for event counting.

### TM Interrupts

The two different types of TMs have two internal interrupts, the internal comparator A or comparator P, which generates a TM interrupt when a compare match condition occurs. When a TM interrupt is generated, it can be used to clear the counter and also to change the state of the TM output pin.

#### **TM External Pins**

Each of the TMs, irrespective of what type, has one TM input pin, with the label xTCK. The TM input pin, is essentially a clock source for the TM and is selected using the xTCK2~ xTCK0 bits in the xTMC0 register. This external TM input pin allows an external clock source to drive the internal TM. The TM input pin can be chosen to have either a rising or falling active edge. The STCK and PTCK pins are also used as the external trigger input pin in single pulse output mode.

Another pin xTP, which also can be the xTM output pin, is the capture input pin whose active edge can be a rising edge, a falling edge or both rising and falling edges. The active edge transition type is selected using the xTIO1~xTIO0 bits in the xTMC1 register. For the PTM, there is another capture input, PTCK, for PTM capture input mode, which can be used as the external trigger input source except for the PTP pin.

The TMs each have two output pins, named xTP. The TM output pins can be selected using the corresponding pin-shared function selection bits described in the Pin-shared Function section. When the TM is in the Compare Match Output Mode, these pins can be controlled by the TM to switch to a high or low level or to toggle when a compare match situation occurs. The external xTP output pin is also the pin where the TM generates the PWM output waveform.

As the TM input or output pins are pin-shared with other functions, the TM external pin function must first be setup using registers. A single bit in the Pin-shared Function Selection Registers determines if its associated pin is to be used as an external TM pin or if it is to have another function.

| SI          | ГМ     | PTM         |        |  |
|-------------|--------|-------------|--------|--|
| Input       | Output | Input       | Output |  |
| STCK or STP | STP    | PTCK or PTP | PTP    |  |

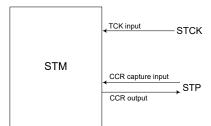

TM External Pins

Rev. 1.50 67 October 26, 2023

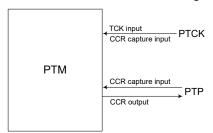

## TM Input/Output Pin Selection

Selecting to have a TM input/output or whether to retain its other shared function is implemented using the relevant pin-shared function selection registers, with the corresponding selection bits in each pin-shared function register corresponding to a TM input/output pin. Configuring the selection bits correctly will setup the corresponding pin as a TM input/output. The details of the pin-shared function selection are described in the Pin-shared Function section.

**STM Function Pin Control Block Diagram** 

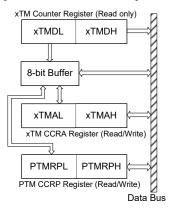

**PTM Function Pin Control Block Diagram** 

# **Programming Considerations**

The TM Counter Registers and the Capture/Compare CCRA and CCRP registers, all have a low and high byte structure. The high bytes can be directly accessed, but as the low bytes can only be accessed via an internal 8-bit buffer, reading or writing to these register pairs must be carried out in a specific way. The important point to note is that data transfer to and from the 8-bit buffer and its related low byte only takes place when a write or read operation to its corresponding high byte is executed.

As the CCRA and CCRP registers are implemented in the way shown in the following diagram and accessing the register is carried out in a specific way described above, it is recommended to use the "MOV" instruction to access the CCRA and CCRP low byte registers, named xTMAL and PTMRPL, using the following access procedures. Accessing the CCRA or CCRP low byte register without following these access procedures will result in unpredictable values.

Rev. 1.50 68 October 26, 2023

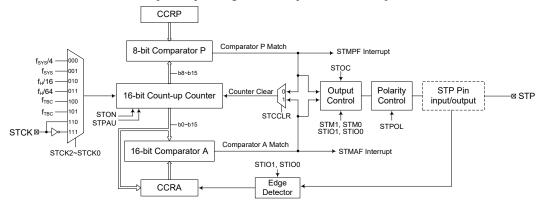

The following steps show the read and write procedures:

- · Writing Data to CCRA or CCRP
  - Step 1. Write data to Low Byte xTMAL or PTMRPL
    - Note that here data is only written to the 8-bit buffer.
  - Step 2. Write data to High Byte xTMAH or PTMRPH
    - Here data is written directly to the high byte registers and simultaneously data is latched from the 8-bit buffer to the Low Byte registers.
- · Reading Data from the Counter Registers and CCRA or CCRP
  - Step 1. Read data from the High Byte xTMDH, xTMAH or PTMRPH
    - Here data is read directly from the High Byte registers and simultaneously data is latched from the Low Byte register into the 8-bit buffer.
  - Step 2. Read data from the Low Byte xTMDL, xTMAL or PTMRPL
    - This step reads data from the 8-bit buffer.

# Standard Type TM - STM

The Standard Type TM contains five operating modes, which are Compare Match Output, Timer/Event Counter, Capture Input, Single Pulse Output and PWM Output modes.

Note: For the HT45F5N, the STP pin is not bounded to the external package.

### Standard Type TM Block Diagram

### **Standard TM Operation**

The size of Standard TM is 16-bit wide and its core is a 16-bit count-up counter which is driven by a user selectable internal or external clock source. There are two internal comparators with the names, Comparator A and Comparator P. These comparators will compare the value in the counter with CCRP and CCRA registers. The CCRP is 8-bit wide whose value is compared with the highest 8 bits in the counter while the CCRA is the 16 bits and therefore compares with all counter bits.

The only way of changing the value of the 16-bit counter using the application program, is to clear the counter by changing the STON bit from low to high. The counter will also be cleared automatically by a counter overflow or a compare match with one of its associated comparators. When these conditions occur, a STM interrupt signal will also usually be generated. The Standard Type TM can operate in a number of different operational modes, can be driven by different clock sources and can also control an output pin. All operating setup conditions are selected using relevant internal registers.

Rev. 1.50 69 October 26, 2023

### Standard Type TM Registers

Overall operation of the Standard TM is controlled using a series of registers. A read only register pair exists to store the internal counter 16-bit value, while a read/write register pair exists to store the internal 16-bit CCRA value. One register STMRP is used to store the 8-bit CCRP value. The remaining two registers are control registers which setup the different operating and control modes.

| Register |       |       |       | В     | it   |       |       |        |

16-bit Standard TM Register List

#### STMC0 Register

| Bit  | 7     | 6     | 5     | 4     | 3    | 2 | 1 | 0 |
|------|-------|-------|-------|-------|------|---|---|---|
| Name | STPAU | STCK2 | STCK1 | STCK0 | STON | _ | _ | _ |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W  | _ | _ | _ |
| POR  | 0     | 0     | 0     | 0     | 0    | _ | _ | _ |

Bit 7 STPAU: STM Counter Pause Control

0: Run 1: Pause

The counter can be paused by setting this bit high. Clearing the bit to zero restores normal counter operation. When in a Pause condition the STM will remain powered up and continue to consume power. The counter will retain its residual value when this bit changes from low to high and resume counting from this value when the bit changes to a low value again.

### Bit 6~4 STCK2~STCK0: Select STM Counter clock

 $\begin{array}{c} 000: \ f_{SYS}/4 \\ 001: \ f_{SYS} \\ 010: \ f_H/16 \\ 011: \ f_H/64 \\ 100: \ f_{TBC} \\ 101: \ f_{TBC} \end{array}$ 

110: STCK rising edge clock 111: STCK falling edge clock

These three bits are used to select the clock source for the STM. The external pin clock source can be chosen to be active on the rising or falling edge. The clock source  $f_{SYS}$  is the system clock, while  $f_H$  and  $f_{TBC}$  are other internal clocks, the details of which can be found in the oscillator section.

### Bit 3 STON: STM Counter On/Off Control

0: Off 1: On

This bit controls the overall on/off function of the STM. Setting the bit high enables the counter to run, clearing the bit disables the STM. Clearing this bit to zero will stop the counter from counting and turn off the STM which will reduce its power consumption. When the bit changes state from low to high the internal counter value will be reset to zero, however when the bit changes from high to low, the internal counter will retain its residual value until the bit returns high again. If the STM is in the Compare Match

Rev. 1.50 October 26, 2023

Output Mode or the PWM output Mode or Single Pulse Output Mode then the STM output pin will be reset to its initial condition, as specified by the STOC bit, when the STON bit changes from low to high.

Bit 2~0 Unimplemented, read as "0"

#### STMC1 Register

| Bit  | 7    | 6    | 5     | 4     | 3    | 2     | 1     | 0      |
|------|------|------|-------|-------|------|-------|-------|--------|
| Name | STM1 | STM0 | STIO1 | STIO0 | STOC | STPOL | STDPX | STCCLR |
| R/W  | R/W  | R/W  | R/W   | R/W   | R/W  | R/W   | R/W   | R/W    |
| POR  | 0    | 0    | 0     | 0     | 0    | 0     | 0     | 0      |

Bit 7~6 STM1~ STM0: Select STM Operating Mode

00: Compare Match Output Mode

01: Capture Input Mode

10: PWM output Mode or Single Pulse Output Mode

11: Timer/Counter Mode

These bits setup the required operating mode for the STM. To ensure reliable operation the STM should be switched off before any changes are made to the STM1 and STM0 bits. In the Timer/Counter Mode, the STM output pin state is undefined.

Bit 5~4 STIO1~ STIO0: Select STM external pin function

Compare Match Output Mode

00: No change

01: Output low

10: Output high

11: Toggle output

PWM output Mode/ Single Pulse Output Mode

00: PWM Output inactive state

01: PWM Output active state

10: PWM output

11: Single pulse output

Capture Input Mode

00: Input capture at rising edge of STP

01: Input capture at falling edge of STP

10: Input capture at falling/rising edge of STP

11: Input capture disabled

Timer/counter Mode:

Unused

These two bits are used to determine how the STM output pin changes state when a certain condition is reached. The function that these bits select depends upon in which mode the STM is running.

In the Compare Match Output Mode, the STIO1~STIO0 bits determine how the STM output pin changes state when a compare match occurs from the Comparator A. The TM output pin can be setup to switch high, switch low or to toggle its present state when a compare match occurs from the Comparator A. When the STIO1~STIO0 bits are both zero, then no change will take place on the output. The initial value of the TM output pin should be setup using the STOC bit. Note that the output level requested by the STIO1~STIO0 bits must be different from the initial value setup using the STOC bit otherwise no change will occur on the TM output pin when a compare match occurs. After the TM output pin changes state, it can be reset to its initial level by changing the level of the STON bit from low to high.

In the PWM Mode, the STIO1 and STIO0 bits determine how the TM output pin changes state when a certain compare match condition occurs. The PWM output function is modified by changing these two bits. It is necessary to change the values of the STIO1 and STIO0 bits only after the TM has been switched off. Unpredictable PWM outputs will occur if the STIO1 and STIO0 bits are changed when the TM is running.

Bit 3 STOC: STM output pin control bit

Compare Match Output Mode

0: Initial low 1: Initial high

PWM output Mode/ Single Pulse Output Mode

0: Active low 1: Active high

This is the output control bit for the STM output pin. Its operation depends upon whether STM is being used in the Compare Match Output Mode or in the PWM output Mode/ Single Pulse Output Mode. It has no effect if the STM is in the Timer/Counter Mode. In the Compare Match Output Mode it determines the logic level of the STM output pin before a compare match occurs. In the PWM output Mode it determines if the PWM signal is active high or active low. In the Single Pulse Output Mode it determines the logic level of the STM output pin when the STON bit changes from low to high.

Bit 2 STPOL: STM Output polarity Control

0: Non-invert

1: Invert

This bit controls the polarity of the STM output pin. When the bit is set high the STM output pin will be inverted and not inverted when the bit is zero. It has no effect if the STM is in the Timer/Counter Mode.

Bit 1 STDPX: STM PWM period/duty Control

0: CCRP – period; CCRA - duty 1: CCRP – duty; CCRA - period

This bit determines which of the CCRA and CCRP registers are used for period and duty control of the PWM waveform.

Bit 0 STCCLR: Select STM Counter clear condition selection

0: Comparator P match

1: Comparator A match

This bit is used to select the method which clears the counter. Remember that the Standard TM contains two comparators, Comparator A and Comparator P, either of which can be selected to clear the internal counter. With the STCCLR bit set high, the counter will be cleared when a compare match occurs from the Comparator A. When the bit is low, the counter will be cleared when a compare match occurs from the Comparator P or with a counter overflow. A counter overflow clearing method can only be implemented if the CCRP bits are all cleared to zero. The STCCLR bit is not used in the PWM output mode, Single Pulse or Input Capture Mode.

Bit  $7 \sim 0$  **D7~D0**: STM CCRP 8-bit register, compared with the STM Counter bit  $15 \sim$  bit 8. Comparator P Match Period =

0: 65536 STM clocks

 $1\sim255:256\times(1\sim255)$  STM clocks

These eight bits are used to setup the value on the internal CCRP 8-bit register, which are then compared with the internal counters highest eight bits. The result of this comparison can be selected to clear the internal counter if the STCCLR bit is cleared to zero. Clearing the STCCLR bit to zero ensures that a compare match with the CCRP values will reset the internal counter. As the CCRP bits are only compared with the highest eight counter bits, the compare values exist in 256 clock cycle multiples. Clearing all eight bits to zero is in effect allowing the counter to overflow at its maximum value.

## Standard Type TM Operating Modes

The Standard Type TM can operate in one of five operating modes, Compare Match Output Mode, PWM Output Mode, Single Pulse Output Mode, Capture Input Mode or Timer/Counter Mode. The operating mode is selected using the STM1 and STM0 bits in the STMC1 register.

#### **Compare Output Mode**

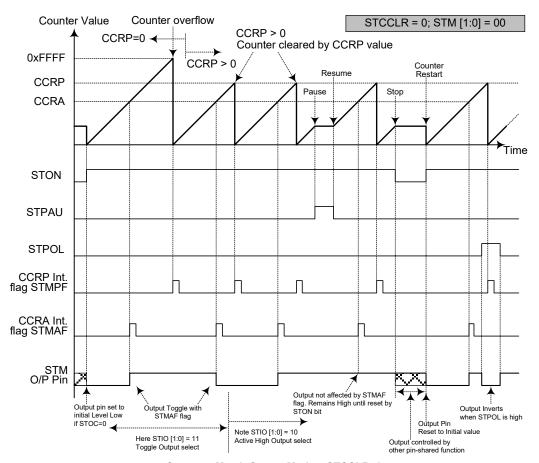

To select this mode, bits STM1 and STM0 in the STMC1 register, should be set to 00 respectively. In this mode once the counter is enabled and running it can be cleared by three methods. These are a counter overflow, a compare match from Comparator A and a compare match from Comparator P. When the STCCLR bit is low, there are two ways in which the counter can be cleared. One is when a compare match from Comparator P, the other is when the CCRP bits are all zero which allows the counter to overflow. Here both STMAF and STMPF interrupt request flags for Comparator A and Comparator P respectively, will both be generated.

If the STCCLR bit in the STMC1 register is high then the counter will be cleared when a compare match occurs from Comparator A. However, here only the STMAF interrupt request flag will be generated even if the value of the CCRP bits is less than that of the CCRA registers. Therefore when STCCLR is high no STMPF interrupt request flag will be generated. In the Compare Match Output Mode, the CCRA cannot be set to "0".

As the name of the mode suggests, after a comparison is made, the STM output pin, will change state. The STM output pin condition however only changes state when an STMAF interrupt request flag is generated after a compare match occurs from Comparator A. The STMPF interrupt request flag, generated from a compare match occurs from Comparator P, will have no effect on the STM output pin. The way in which the STM output pin changes state are determined by the condition of the STIO1 and STIO0 bits in the STMC1 register. The STM output pin can be selected using the STIO1 and STIO0 bits to go high, to go low or to toggle from its present condition when a compare match occurs from Comparator A. The initial condition of the STM output pin, which is setup after the STON bit changes from low to high, is setup using the STOC bit. Note that if the STIO1 and STIO0 bits are zero then no pin change will take place.

Rev. 1.50 74 October 26, 2023

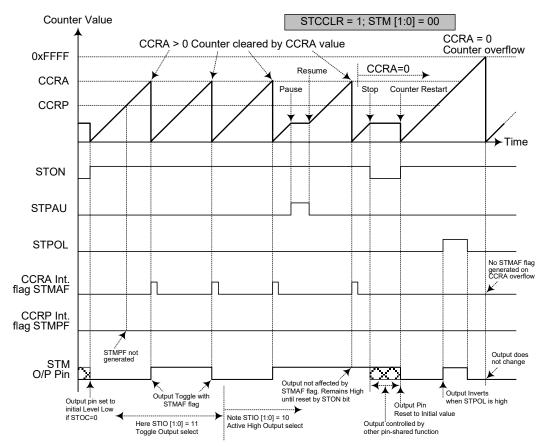

Compare Match Output Mode - STCCLR=0

Note: 1. With STCCLR=0 a Comparator P match will clear the counter

- 2. The TM output pin controlled only by the STMAF flag
- 3. The output pin reset to initial state by a STON bit rising edge

Compare Match Output Mode - STCCLR=1

Note: 1. With STCCLR=1 a Comparator A match will clear the counter

- 2. The STM output pin controlled only by the STMAF flag
- 3. The output pin reset to initial state by a STON rising edge
- 4. The STMPF flag is not generated when STCCLR=1

Rev. 1.50 76 October 26, 2023

#### **Timer/Counter Mode**

To select this mode, bits STM1 and STM0 in the STMC1 register should be set to 11 respectively. The Timer/Counter Mode operates in an identical way to the Compare Match Output Mode generating the same interrupt flags. The exception is that in the Timer/Counter Mode the STM output pin is not used. Therefore the above description and Timing Diagrams for the Compare Match Output Mode can be used to understand its function. As the STM output pin is not used in this mode, the pin can be used as a normal I/O pin or other pin-shared function by setting pin-share function register.

#### **PWM Output Mode**

To select this mode, bits STM1 and STM0 in the STMC1 register should be set to 10 respectively and also the STIO1 and STIO0 bits should be set to 10 respectively. The PWM function within the STM is useful for applications which require functions such as motor control, heating control, illumination control etc. By providing a signal of fixed frequency but of varying duty cycle on the STM output pin, a square wave AC waveform can be generated with varying equivalent DC RMS relies.

As both the period and duty cycle of the PWM waveform can be controlled, the choice of generated waveform is extremely flexible. In the PWM output mode, the STCCLR bit has no effect as the PWM period. Both of the CCRA and CCRP registers are used to generate the PWM waveform, one register is used to clear the internal counter and thus control the PWM waveform frequency, while the other one is used to control the duty cycle. Which register is used to control either frequency or duty cycle is determined using the STDPX bit in the STMC1 register. The PWM waveform frequency and duty cycle can therefore be controlled by the values in the CCRA and CCRP registers.

An interrupt flag, one for each of the CCRA and CCRP, will be generated when a compare match occurs from either Comparator A or Comparator P. The STOC bit in the STMC1 register is used to select the required polarity of the PWM waveform while the two STIO1 and STIO0 bits are used to enable the PWM output or to force the STM output pin to a fixed high or low level. The STPOL bit is used to reverse the polarity of the PWM output waveform.

#### 16-bit STM, PWM Mode, Edge-aligned Mode, STDPX=0

| CCRP   | 1~255    | 0     |
|--------|----------|-------|
| Period | CCRP×256 | 65536 |
| Duty   | CC       | RA    |

If  $f_{SYS}$ =8MHz, STM clock source is  $f_{SYS}$ /4, CCRP=2 and CCRA=128,

The STM PWM output frequency= $(f_{SYS}/4)/(2\times256)=f_{SYS}/2048=4kHz$ , duty= $128/(2\times256)=25\%$ .

If the Duty value defined by the CCRA register is equal to or greater than the Period value, then the PWM output duty is 100%.

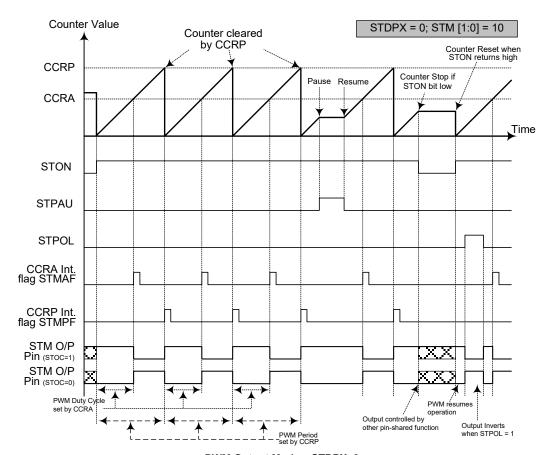

### • 16-bit STM, PWM Mode, Edge-aligned Mode, STDPX=1

| CCRP   | 1~255 0  |       |  |  |
|--------|----------|-------|--|--|
| Period | CCRA     |       |  |  |
| Duty   | CCRP×256 | 65536 |  |  |

The PWM output period is determined by the CCRA register value together with the STM clock while the PWM duty cycle is defined by the CCRP register value except when the CCRP value is equal to 0.

Rev. 1.50 77 October 26, 2023

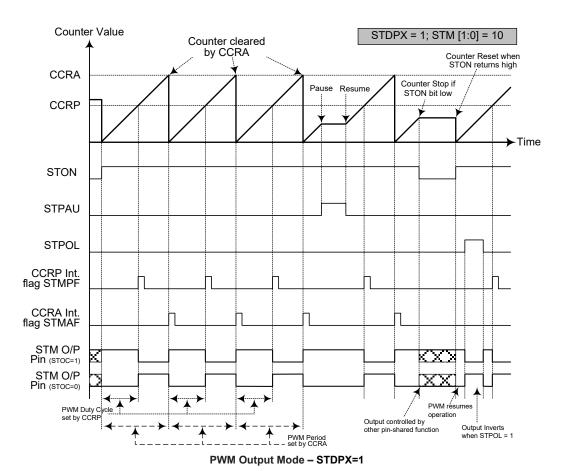

PWM Output Mode - STDPX=0

Note: 1. Here STDPX=0 - Counter cleared by CCRP

- 2. A counter clear sets the PWM Period
- 3. The internal PWM function continues running even when STIO[1:0]=00 or 01
- 4. The STCCLR bit has no influence on PWM operation

Rev. 1.50 October 26, 2023

Note: 1. Here STDPX=1 – Counter cleared by CCRA

- 2. A counter clear sets PWM Period
- 3. The internal PWM function continues even when STIO[1:0]=00 or 01
- 4. The STCCLR bit has no influence on PWM operation

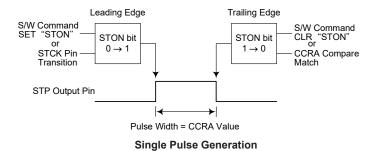

#### Single Pulse Mode

To select this mode, bits STM1 and STM0 in the STMC1 register should be set to 10 respectively and also the STIO1 and STIO0 bits should be set to 11 respectively. The Single Pulse Output Mode, as the name suggests, will generate a single shot pulse on the STM output pin.

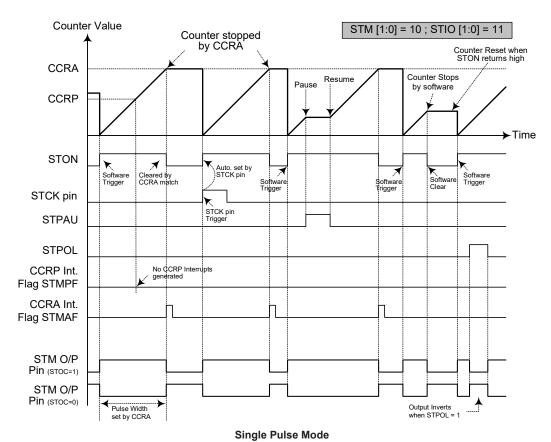

The trigger for the pulse output leading edge is a low to high transition of the STON bit, which can be implemented using the application program. However in the Single Pulse Mode, the STON bit can also be made to automatically change from low to high using the external STCK pin, which will in turn initiate the Single Pulse output. When the STON bit transitions to a high level, the counter will start running and the pulse leading edge will be generated. The STON bit should remain high when the pulse is in its active state. The generated pulse trailing edge will be generated when the STON bit is cleared to zero, which can be implemented using the application program or when a compare match occurs from Comparator A.

However a compare match from Comparator A will also automatically clear the STON bit and thus generate the Single Pulse output trailing edge. In this way the CCRA value can be used to control the pulse width. A compare match from Comparator A will also generate a STM interrupt. The counter can only be reset back to zero when the STON bit changes from low to high when the counter restarts. In the Single Pulse Mode CCRP is not used. The STCCLR and STDPX bits are not used in this Mode.

Rev. 1.50 80 October 26, 2023

Note: 1. Counter stopped by CCRA match

- 2. CCRP is not used
- 3. The pulse is triggered by the STCK pin or setting the STON bit high
- 4. In the Single Pulse Mode, STIO [1:0] must be set to "11" and cannot be changed.

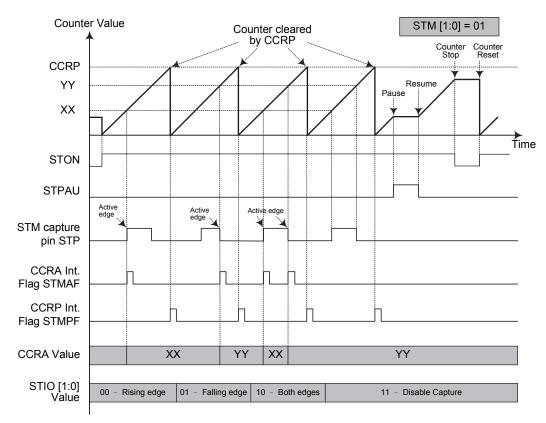

## **Capture Input Mode**

To select this mode bits STM1 and STM0 in the STMC1 register should be set to 01 respectively. This mode enables external signals to capture and store the present value of the internal counter and can therefore be used for applications such as pulse width measurement. The external signal is supplied on the STP, whose active edge can be either a rising edge, a falling edge or both rising and falling edges; the active edge transition type is selected using the STIO1 and STIO0 bits in the STMC1 register. The counter is started when the STON bit changes from low to high which is initiated using the application program.

When the required edge transition appears on the STP the present value in the counter will be latched into the CCRA registers and a STM interrupt generated. Irrespective of what events occur on the STP the counter will continue to free run until the STON bit changes from high to low. When a CCRP compare match occurs the counter will reset back to zero; in this way the CCRP value can be used to control the maximum counter value. When a CCRP compare match occurs from Comparator P, a STM interrupt will also be generated. Counting the number of overflow interrupt signals from the CCRP can be a useful method in measuring long pulse widths. The STIO1 and STIO0 bits can select the active trigger edge on the STP to be a rising edge, falling edge or both edge types. If the STIO1 and STIO0 bits are both set high, then no capture operation will take place irrespective of what happens on the STP, however it must be noted that the counter will continue to run. The STCCLR and STDPX bits are not used in this Mode.

Rev. 1.50 82 October 26, 2023

### **Capture Input Mode**

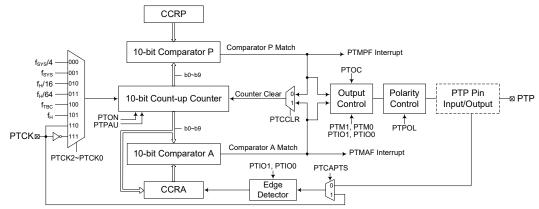

Note: 1. STM[1:0]=01 and active edge set by the STIO[1:0] bits

- 2. A TM Capture input pin active edge transfers the counter value to CCRA
- 3. The STCCLR and STDPX bits are not used
- 4. No output function STOC and STPOL bits are not used
- 5. CCRP determines the counter value and the counter has a maximum count value when CCRP is equal to zero.

# Periodic Type TM - PTM

The Periodic Type TM contains five operating modes, which are Compare Match Output, Timer/Event Counter, Capture Input, Single Pulse Output and PWM Output modes.

Periodic Type TM Block Diagram

# **Periodic TM Operation**

The Periodic Type TM core is a 10-bit count-up counter which is driven by a user selectable internal or external clock source. There are also two internal comparators with the names, Comparator A and Comparator P. These comparators will compare the value in the counter with CCRP and CCRA registers. The CCRP comparator is 10-bit wide.

The only way of changing the value of the 10-bit counter using the application program, is to clear the counter by changing the PTON bit from low to high. The counter will also be cleared automatically by a counter overflow or a compare match with one of its associated comparators. When these conditions occur, a PTM interrupt signal will also usually be generated. The Periodic Type TM can operate in a number of different operational modes, can be driven by different clock sources including an input pin and can also control more than one output pin. All operating setup conditions are selected using relevant internal registers.

# **Periodic Type TM Register Description**

Overall operation of the Periodic Type TM is controlled using a series of registers. A read only register pair exists to store the internal counter 10-bit value, while two read/write register pairs exist to store the internal 10-bit CCRA value and CCRP value. The remaining two registers are control registers which setup the different operating and control modes.

10-bit Periodic TM Register List

Rev. 1.50 84 October 26, 2023

### PTMC0 Register

| Bit  | 7     | 6     | 5     | 4     | 3    | 2 | 1 | 0 |
|------|-------|-------|-------|-------|------|---|---|---|
| Name | PTPAU | PTCK2 | PTCK1 | PTCK0 | PTON | _ | _ | _ |
| R/W  | R/W   | R/W   | R/W   | R/W   | R/W  | _ | _ | _ |
| POR  | 0     | 0     | 0     | 0     | 0    | _ | _ | _ |

Bit 7 **PTPAU**: PTM Counter Pause Control

0: Run 1: Pause

The counter can be paused by setting this bit high. Clearing the bit to zero restores normal counter operation. When in a Pause condition the PTM will remain powered up and continue to consume power. The counter will retain its residual value when this bit changes from low to high and resume counting from this value when the bit changes to a low value again.

Bit 6~4 PTCK2~PTCK0: Select PTM Counter clock

 $\begin{array}{c} 000: \, f_{SYS}/4 \\ 001: \, f_{SYS} \\ 010: \, f_H/16 \\ 011: \, f_H/64 \\ 100: \, f_{TBC} \\ 101: \, f_H \end{array}$ 

110: PTCK rising edge clock111: PTCK falling edge clock

These three bits are used to select the clock source for the PTM. The external pin clock source can be chosen to be active on the rising or falling edge. The clock source  $f_{SYS}$  is the system clock, while  $f_H$  and  $f_{TBC}$  are other internal clocks, the details of which can be found in the oscillator section.

Bit 3 PTON: PTM Counter On/Off Control

0: Off 1: On

This bit controls the overall on/off function of the PTM. Setting the bit high enables the counter to run, clearing the bit disables the PTM. Clearing this bit to zero will stop the counter from counting and turn off the PTM which will reduce its power consumption. When the bit changes state from low to high the internal counter value will be reset to zero, however when the bit changes from high to low, the internal counter will retain its residual value until the bit returns high again.

If the PTM is in the Compare Match Output Mode, PWM output Mode or Single Pulse Output Mode then the PTM output pin will be reset to its initial condition, as specified by the PTOC bit, when the PTON bit changes from low to high.

Bit 2~0 Unimplemented, read as "0"

#### PTMC1 Register

| Bit  | 7    | 6    | 5     | 4     | 3    | 2     | 1       | 0      |
|------|------|------|-------|-------|------|-------|---------|--------|
| Name | PTM1 | PTM0 | PTIO1 | PTIO0 | PTOC | PTPOL | PTCAPTS | PTCCLR |
| R/W  | R/W  | R/W  | R/W   | R/W   | R/W  | R/W   | R/W     | R/W    |
| POR  | 0    | 0    | 0     | 0     | 0    | 0     | 0       | 0      |

Bit 7~6 **PTM1~PTM0**: Select PTM Operating Mode

00: Compare Match Output Mode

01: Capture Input Mode

10: PWM Mode or Single Pulse Output Mode

11: Timer/Counter Mode

These bits setup the required operating mode for the PTM. To ensure reliable operation the PTM should be switched off before any changes are made to the PTM1 and PTM0 bits. In the Timer/Counter Mode, the PTM output pin control must be disabled.

#### Bit 5~4 **PTIO1~PTIO0**: Select PTM external pin function

Compare Match Output Mode

00: No change

01: Output low

10: Output high

11: Toggle output

PWM Mode/Single Pulse Output Mode

00: PWM Output inactive state

01: PWM Output active state

10: PWM output

11: Single pulse output

#### Capture Input Mode

00: Input capture at rising edge of PTP or PTCK

01: Input capture at falling edge of PTP or PTCK

10: Input capture at falling/rising edge of PTP or PTCK

11: Input capture disabled

Timer/Counter Mode

Unused

These two bits are used to determine how the PTM output pin changes state when a certain condition is reached. The function that these bits select depends upon in which mode the PTM is running.

In the Compare Match Output Mode, the PTIO1 and PTIO0 bits determine how the PTM output pin changes state when a compare match occurs from the Comparator A. The PTM output pin can be setup to switch high, switch low or to toggle its present state when a compare match occurs from the Comparator A. When the bits are both zero, then no change will take place on the output. The initial value of the PTM output pin should be setup using the PTOC bit in the PTMC1 register. Note that the output level requested by the PTIO1 and PTIO0 bits must be different from the initial value setup using the PTOC bit otherwise no change will occur on the PTM output pin when a compare match occurs. After the PTM output pin changes state, it can be reset to its initial level by changing the level of the PTON bit from low to high.

In the PWM Mode, the PTIO1 and PTIO0 bits determine how the PTM output pin changes state when a certain compare match condition occurs. The PWM output function is modified by changing these two bits. It is necessary to only change the values of the PTIO1 and PTIO0 bits only after the TM has been switched off. Unpredictable PWM outputs will occur if the PTIO1 and PTIO0 bits are changed when the PTM is running.

### Bit 3 **PTOC**: PTM PTP Output control bit

Compare Match Output Mode

0: Initial low

1: Initial high

PWM Mode/Single Pulse Output Mode

0: Active low

1: Active high

This is the output control bit for the PTM output pin. Its operation depends upon whether PTM is being used in the Compare Match Output Mode or in the PWM Mode/ Single Pulse Output Mode. It has no effect if the PTM is in the Timer/Counter Mode. In the Compare Match Output Mode it determines the logic level of the PTM output pin before a compare match occurs. In the PWM Mode it determines if the PWM signal is active high or active low.

# Bit 2 PTPOL: PTM PTP Output polarity Control

0: Non-invert

1: Invert

This bit controls the polarity of the PTP output pin. When the bit is set high the PTM output pin will be inverted and not inverted when the bit is zero. It has no effect if the PTM is in the Timer/Counter Mode.

Rev. 1.50 86 October 26, 2023

Bit 1 PTCAPTS: PTM Capture Trigger Source Selection

0: From PTP pin 1: From PTCK pin

Bit 0 PTCCLR: Select PTM Counter clear condition

0: Comparator P match1: Comparator A match

This bit is used to select the method which clears the counter. Remember that the Periodic TM contains two comparators, Comparator A and Comparator P, either of which can be selected to clear the internal counter. With the PTCCLR bit set high, the counter will be cleared when a compare match occurs from the Comparator A. When the bit is low, the counter will be cleared when a compare match occurs from the Comparator P or with a counter overflow. A counter overflow clearing method can only be implemented if the CCRP bits are all cleared to zero. The PTCCLR bit is not used in the PWM Mode, Single Pulse or Capture Input Mode.

PTM 10-bit CCRP bit 9 ~ bit 8

# **Periodic Type TM Operating Modes**

The Standard Type TM can operate in one of five operating modes, Compare Match Output Mode, PWM Output Mode, Single Pulse Output Mode, Capture Input Mode or Timer/Counter Mode. The operating mode is selected using the PTM1 and PTM0 bits in the PTMC1 register.

## **Compare Output Mode**

To select this mode, bits PTM1 and PTM0 in the PTMC1 register, should be set to 00 respectively. In this mode once the counter is enabled and running it can be cleared by three methods. These are a counter overflow, a compare match from Comparator A and a compare match from Comparator P. When the PTCCLR bit is low, there are two ways in which the counter can be cleared. One is when a compare match from Comparator P, the other is when the CCRP bits are all zero which allows the counter to overflow. Here both PTMAF and PTMPF interrupt request flags for Comparator A and Comparator P respectively, will both be generated.

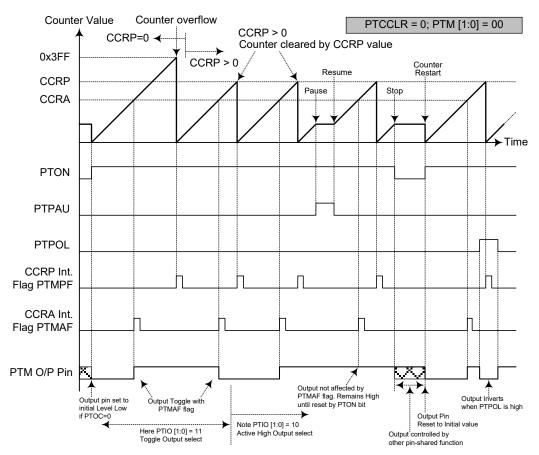

If the PTCCLR bit in the PTMC1 register is high then the counter will be cleared when a compare match occurs from Comparator A. However, here only the PTMAF interrupt request flag will be generated even if the value of the CCRP bits is less than that of the CCRA registers. Therefore when PTCCLR is high no PTMPF interrupt request flag will be generated. In the Compare Match Output Mode, the CCRA can not be cleared to zero.

If the CCRA bits are all zero, the counter will overflow when its reaches its maximum 10-bit, 3FF Hex, value, however here the PTMAF interrupt request flag will not be generated.

As the name of the mode suggests, after a comparison is made, the PTM output pin, will change state. The PTM output pin condition however only changes state when a PTMAF interrupt request flag is generated after a compare match occurs from Comparator A. The PTMPF interrupt request flag, generated from a compare match occurs from Comparator P, will have no effect on the PTM output pin. The way in which the PTM output pin changes state are determined by the condition of the PTIO1 and PTIO0 bits in the PTMC1 register. The PTM output pin can be selected using the PTIO1 and PTIO0 bits to go high, to go low or to toggle from its present condition when a compare match occurs from Comparator A. The initial condition of the PTM output pin, which is setup after the PTON bit changes from low to high, is setup using the PTOC bit. Note that if the PTIO1 and PTIO0 bits are zero then no pin change will take place.

Rev. 1.50 88 October 26, 2023

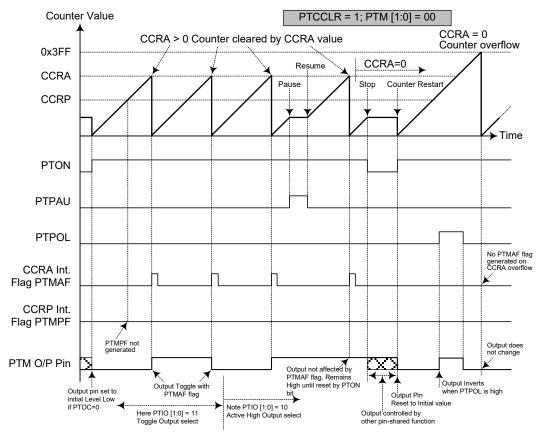

Compare Match Output Mode - PTCCLR=0

Note: 1. With PTCCLR=0 a Comparator P match will clear the counter

- 2. The TM output pin is controlled only by the PTMAF flag
- 3. The output pin is reset to its initial state by a PTON bit rising edge

Compare Match Output Mode - PTCCLR=1

Note: 1. With PTCCLR=1 a Comparator A match will clear the counter

- 2. The TM output pin is controlled only by the PTMAF flag
- 3. The output pin is reset to its initial state by a PTON bit rising edge
- 4. A PTMPF flag is not generated when PTCCLR=1

Rev. 1.50 90 October 26, 2023

#### **Timer/Counter Mode**

To select this mode, bits PTM1 and PTM0 in the PTMC1 register should be set to 11 respectively. The Timer/Counter Mode operates in an identical way to the Compare Match Output Mode generating the same interrupt flags. The exception is that in the Timer/Counter Mode the TM output pin is not used. Therefore the above description and Timing Diagrams for the Compare Match Output Mode can be used to understand its function. As the TM output pin is not used in this mode, the pin can be used as a normal I/O pin or other pin-shared function.

#### **PWM Output Mode**

To select this mode, bits PTM1 and PTM0 in the PTMC1 register should be set to 10 respectively. The PWM function within the PTM is useful for applications which require functions such as motor control, heating control, illumination control etc. By providing a signal of fixed frequency but of varying duty cycle on the PTM output pin, a square wave AC waveform can be generated with varying equivalent DC RMS values.

As both the period and duty cycle of the PWM waveform can be controlled, the choice of generated waveform is extremely flexible. In the PWM Output Mode, the PTCCLR bit has no effect on the PWM operation. Both of the CCRA and CCRP registers are used to generate the PWM waveform, one register is used to clear the internal counter and thus control the PWM waveform frequency, while the other one is used to control the duty cycle. The PWM waveform frequency and duty cycle can therefore be controlled by the values in the CCRA and CCRP registers.

An interrupt flag, one for each of the CCRA and CCRP, will be generated when a compare match occurs from either Comparator A or Comparator P. The PTOC bit in the PTMC1 register is used to select the required polarity of the PWM waveform while the two PTIO1 and PTIO0 bits are used to enable the PWM output or to force the PTM output pin to a fixed high or low level. The PTPOL bit is used to reverse the polarity of the PWM output waveform.

## 10-bit PTM, PWM Mode, Edge-aligned Mode

| CCRP   | 1~1023 | 0    |
|--------|--------|------|
| Period | 1~1023 | 1024 |
| Duty   | CC     | RA   |

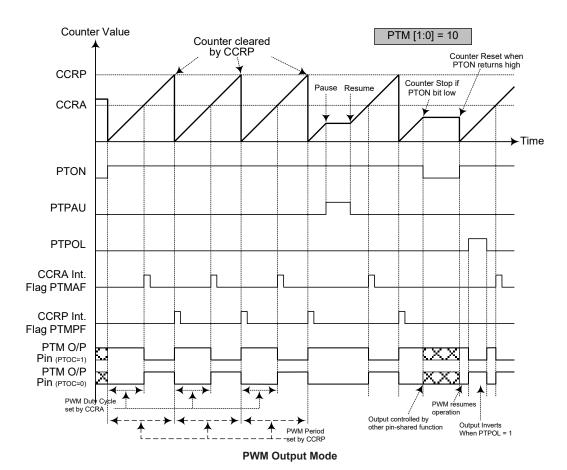

If f<sub>SYS</sub>=8MHz, PTM clock source select f<sub>SYS</sub>/4, CCRP=512 and CCRA=128,

The PTM PWM output frequency= $(f_{SYS}/4)/512=f_{SYS}/2048=4$ kHz, duty=128/512=25%.

If the Duty value defined by the CCRA register is equal to or greater than the Period value, then the PWM output duty is 100%.

Rev. 1.50 91 October 26, 2023

Note: 1. Counter cleared by CCRP

- 2. A counter clear sets the PWM Period
- 3. The internal PWM function continues running even when PTIO [1:0]=00 or 01
- 4. The PTCCLR bit has no influence on PWM operation

Rev. 1.50 92 October 26, 2023

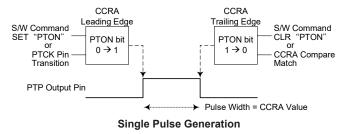

## Single Pulse Mode

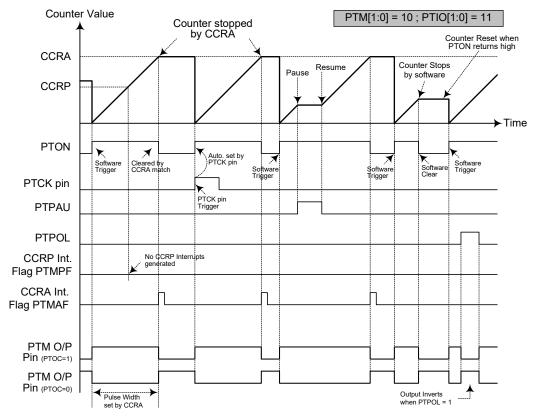

To select this mode, bits PTM1 and PTM0 in the PTMC1 register should be set to 10 respectively and also the PTIO1 and PTIO0 bits should be set to 11 respectively. The Single Pulse Output Mode, as the name suggests, will generate a single shot pulse on the PTM output pin.

The trigger for the pulse output leading edge is a low to high transition of the PTON bit, which can be implemented using the application program. However in the Single Pulse Mode, the PTON bit can also be made to automatically change from low to high using the external PTCK pin, which will in turn initiate the Single Pulse output. When the PTON bit transitions to a high level, the counter will start running and the pulse leading edge will be generated. The PTON bit should remain high when the pulse is in its active state. The generated pulse trailing edge will be generated when the PTON bit is cleared to zero, which can be implemented using the application program or when a compare match occurs from Comparator A.

However a compare match from Comparator A will also automatically clear the PTON bit and thus generate the Single Pulse output trailing edge. In this way the CCRA value can be used to control the pulse width. A compare match from Comparator A will also generate a PTM interrupt. The counter can only be reset back to zero when the PTON bit changes from low to high when the counter restarts. In the Single Pulse Mode CCRP is not used. The PTCCLR bit is not used in this Mode.

Single Pulse Mode

Note: 1. Counter stopped by CCRA

- 2. CCRP is not used
- 3. The pulse is triggered by the PTCK pin or by setting the PTON bit high
- 4. A PTCK pin active edge will automatically set the PTON bit high
- 5. In the Single Pulse Mode, PTIO [1:0] must be set to "11" and cannot be changed.

Rev. 1.50 94 October 26, 2023

### **Capture Input Mode**

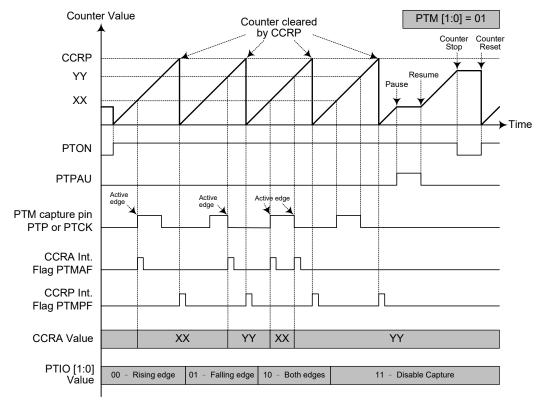

To select this mode bits PTM1 and PTM0 in the PTMC1 register should be set to 01 respectively. This mode enables external signals to capture and store the present value of the internal counter and can therefore be used for applications such as pulse width measurements. The external signal is supplied on the PTP or PTCK pin which is selected using the PTCAPTS bit in the PTMC1 register. The input pin active edge can be either a rising edge, a falling edge or both rising and falling edges; the active edge transition type is selected using the PTIO1 and PTIO0 bits in the PTMC1 register. The counter is started when the PTON bit changes from low to high which is initiated using the application program.

When the required edge transition appears on the PTP or PTCK pin the present value in the counter will be latched into the CCRA registers and a PTM interrupt generated. Irrespective of what events occur on the PTP or PTCK pin, the counter will continue to free run until the PTON bit changes from high to low. When a CCRP compare match occurs the counter will reset back to zero; in this way the CCRP value can be used to control the maximum counter value. When a CCRP compare match occurs from Comparator P, a PTM interrupt will also be generated. Counting the number of overflow interrupt signals from the CCRP can be a useful method in measuring long pulse widths. The PTIO1 and PTIO0 bits can select the active trigger edge on the PTP or PTCK pin to be a rising edge, falling edge or both edge types. If the PTIO1 and PTIO0 bits are both set high, then no capture operation will take place irrespective of what happens on the PTP or PTCK pin, however it must be noted that the counter will continue to run.

As the PTP or PTCK pin is pin shared with other functions, care must be taken if the PTM is in the Capture Input Mode. This is because if the pin is setup as an output, then any transitions on this pin may cause an input capture operation to be executed. The PTCCLR, PTOC and PTPOL bits are not used in this Mode.

Rev. 1.50 95 October 26, 2023

## **Capture Input Mode**

Note: 1. PTM [1:0]=01 and active edge set by the PTIO [1:0] bits

- 2. A PTM Capture input pin active edge transfers the counter value to CCRA
- 3. PTCCLR bit not used
- 4. No output function PTOC and PTPOL bits are not used
- 5. CCRP determines the counter value and the counter has a maximum count value when CCRP is equal to zero.

# **Analog to Digital Converter**

The need to interface to real world analog signals is a common requirement for many electronic systems. However, to properly process these signals by a microcontroller, they must first be converted into digital signals by A/D converters. By integrating the A/D conversion electronic circuitry into the microcontroller, the need for external components is reduced significantly with the corresponding follow-on benefits of lower costs and reduced component space requirements.

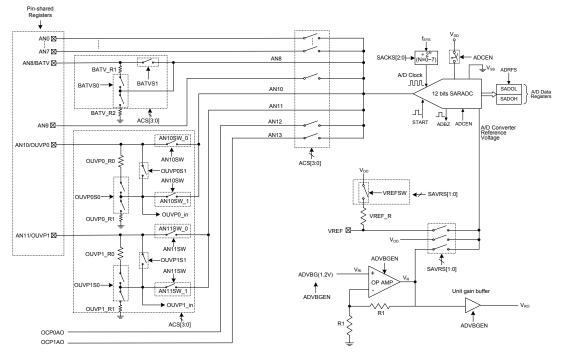

#### A/D Converter Overview

These devices contain a multi-channel analog to digital converter which can directly interface to external analog signals, such as that from sensors or other control signals and convert these signals directly into a 12-bit digital value. It also can convert the internal signals of the Over Current Protection 0 or Over Current Protection 1 OPA output signal into a 12-bit digital value.

The external or internal analog signal to be converted is determined by the ACS3~ACS0 bits. When the external analog signal channel, AN8, AN10 or AN11, is to be converted, the SWS0 or SWS1 register bits together with the ACS3~ACS0 bits should be properly configured to select the required input signals. More detailed information about the A/D input signal is described in the "A/D Converter Control Registers" and "A/D Converter Input Signals" sections respectively.

| E | xternal Input Channels | Internal Signals                              | Channel Select Bits |
|---|------------------------|---|---------------------|
|   | AN0~AN11               | AN12: OCP0 OPA Output<br>AN13:OCP1 OPA Output | ACS3~ACS0           |

The accompanying block diagram shows the overall internal structure of the A/D converter, together with its associated registers.

Note: The Unite-gain buffer output V<sub>RO</sub> can drive the OCPn, OVPn and UVPn DAC.

A/D Converter Structure

Rev. 1.50 97 October 26, 2023

# A/D Converter Register Description

Overall operation of the A/D converter is controlled using several registers. A read only register pair exists to store the A/D converter data 12-bit value. The remaining two registers are control registers which setup the operating and control function of the A/D converter.

| Register       |       |      |         | В      | it     |        |         |         |

A/D Converter Register List

#### A/D Converter Data Registers

As these devices contain an internal 12-bit A/D converter, it requires two data registers to store the converted value. These are a high byte register, known as SADOH, and a low byte register, known as SADOL. After the conversion process takes place, these registers can be directly read by the microcontroller to obtain the digitised conversion value. As only 12 bits of the 16-bit register space is utilised, the format in which the data is stored is controlled by the ADRFS bit in the SADC0 register as shown in the accompanying table. D0~D11 are the A/D conversion result data bits. Any unused bits will be read as zero. Note that A/D data registers contents will be unchanged if the A/D converter is disabled.

| ADRFS | SADOH |     |    |    |     |     |    | SADOL |    |    |    |    |    |    |    |    |
|-------|-------|-----|----|----|-----|-----|----|-------|----|----|----|----|----|----|----|----|
| ADKES | 7     | 6   | 5  | 4  | 3   | 2   | 1  | 0     | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

A/D Data Registers

# A/D Converter Control Registers

To control the function and operation of the A/D converter, two control registers known as SADC0 and SADC1 and two switch control registers, SWS0 and SWS1, are provided. These 8-bit registers define functions such as the selection of which analog channel is connected to the internal A/D converter, the digitised data format, the A/D clock source as well as controlling the start function and monitoring the A/D converter busy status. As these devices contain only one actual analog to digital converter hardware circuit, each of the external or internal analog signal inputs must be routed to the converter. The ACS3~ACS0 bits in the SADC0 register are used to determine which input signal is selected to be converted.

The AN8, AN10 and AN11 input channel each has an integrated voltage divider circuit can be connected or disconnected using the SWS0 and SWS1 registers controlled internal analog switches.

The relevant pin-shared function selection bits determine which pins on I/O Ports are used as analog inputs for the A/D converter input and which pins are not to be used as the A/D converter input. When the pin is selected to be an A/D input, its original function whether it is an I/O or other pin-shared function will be removed. In addition, any internal pull-high resistor connected to the pin will be automatically removed if the pin is selected to be an A/D converter input.

## SADC0 Register

| Bit  | 7     | 6    | 5     | 4     | 3    | 2    | 1    | 0    |
|------|-------|------|-------|-------|------|------|------|------|
| Name | START | ADBZ | ADCEN | ADRFS | ACS3 | ACS2 | ACS1 | ACS0 |
| R/W  | R/W   | R    | R/W   | R/W   | R/W  | R/W  | R/W  | R/W  |
| POR  | 0     | 0    | 0     | 0     | 0    | 0    | 0    | 0    |

START: Start the A/D conversion Bit 7

 $0 \rightarrow 1 \rightarrow 0$ : Start

This bit is used to initiate an A/D conversion process. The bit is normally low but if set high and then cleared low again, the A/D converter will initiate a conversion process.

When the bit is set high the A/D converter will be reset.

Bit 6 ADBZ: A/D converter busy flag

0: No A/D conversion is in progress

1: A/D conversion is in progress

This read only flag is used to indicate whether the A/D conversion is in progress or not. When the START bit is set from low to high and then to low again, the ADBZ flag will be set to 1 to indicate that the A/D conversion is initiated. The ADBZ flag will be cleared to 0 after the A/D conversion is complete.

Bit 5 ADCEN: A/D converter function enable control

> 0: Disable 1: Enable

This bit controls the A/D internal function. This bit should be set to one to enable the A/D converter. If the bit is set low, then the A/D converter will be switched off reducing the device power consumption. When the A/D converter function is disabled, the contents of the A/D data register pair known as SADOH and SADOL will be unchanged.

Bit 4 ADRFS: A/D converter data format select

0: A/D converter data format → SADOH=D[11:4]; SADOL=D[3:0]

1: A/D converter data format → SADOH=D[11:8]; SADOL=D[7:0]

This bit controls the format of the 12-bit converted A/D value in the two A/D data registers. Details are provided in the A/D data register section.

Bit 3~0 ACS3~ACS0: A/D converter input channel select

> 0000: AN0 0001: AN1

0010: AN2

0011: AN3

0100: AN4

0101: AN5

0110: AN6

0111: AN7

1000: AN8

1001: AN9

1010: AN10

1011: AN11

1100: AN12 (from OCP0 OPA output, OCP0AO)

1101: AN13 (from OCP1 OPA output, OCP1AO)

1110: AN0

1111: AN0

## SADC1 Register

| Bit  | 7 | 6 | 5       | 4      | 3      | 2      | 1      | 0      |
|------|---|---|---------|--------|--------|--------|--------|--------|
| Name | _ | _ | ADVBGEN | SAVRS1 | SAVRS0 | SACKS2 | SACKS1 | SACKS0 |
| R/W  | _ | _ | R/W     | R/W    | R/W    | R/W    | R/W    | R/W    |
| POR  | _ | _ | 0       | 0      | 0      | 0      | 0      | 0      |

Bit 7~6 Unimplemented, read as "0"

Bit 5 ADVBGEN: Internal 1.2V Bandgap and OPA (Gain=2) and Unit-gain Buffer enable control

0: Disable 1: Enable

This bit controls the A/D Converter internal 1.2V bandgap and OPA on/off. The 1.2V bandgap voltage can be amplified by 2 times via the internal OPA. Then a 2.4V reference voltage  $V_R$  can be obtained. This bit also controls the enable of the internal unit-gain buffer which drivers the OCPn, OVPn and UVPn D/A Converters. So if one of the functions above is used, this bit should be set high at first.

Bit 4~3 SAVRS1~SAVRS0: A/D converter reference voltage ADC\_V<sub>REF</sub> select

00: Internal A/D converter power, V<sub>DD</sub>

01: From external VREF pin

10: Internal V<sub>R</sub> - 2.4V OPA(Gain=2)output voltage

11: Internal A/D converter power, V<sub>DD</sub>

These two bits are used to selecte the A/D Converter reference voltage. Note that When the internal  $2.4 \mathrm{V} \, \mathrm{V}_R$  is selected as the A/D converter reference voltage, the ADVBGEN bit should be set high to turn on the  $1.2 \mathrm{V}$  bandgap and OPA function.

Bit 2~0 SACKS2~SACKS0: A/D conversion clock select

000: f<sub>SYS</sub> 001: f<sub>SYS</sub>/2 010: f<sub>SYS</sub>/4 011: f<sub>SYS</sub>/8 100: f<sub>SYS</sub>/16 101: f<sub>SYS</sub>/32 110: f<sub>SYS</sub>/64 111: f<sub>SYS</sub>/128

### SWS0 Register

Bit 5

| Bit  | 7 | 6 | 5      | 4      | 3      | 2      | 1       | 0       |
|------|---|---|--------|--------|--------|--------|---------|---------|
| Name | _ | _ | VREFSW | BATVS1 | BATVS0 | AN10SW | OUVP0S1 | OUVP0S0 |
| R/W  | _ | _ | R/W    | R/W    | R/W    | R/W    | R/W     | R/W     |
| POR  | _ | _ | 0      | 0      | 0      | 0      | 0       | 0       |

Bit 7~6 Unimplemented, read as "0"

VREFSW: Internal 1k resistor switch VREFSW control

0: Switch off, VREF R resistor is not connected to VDD

1: Switch on, VREF R resistor is connected to VDD

This bit determines the on/off control for the switch between the VREF\_R resistor and the  $V_{DD}$  voltage. But only when the SAVRS[1:0] bits value is "01B", selecting the VREF pin as the A/D converter reference voltage source, and then set this VREFSW bit high, can the VREF\_R resistor be enabled. Otherwise this switch is always off.

Bit 4 BATVS1: Internal bypass switch BATVS1 control

0: Switch off

1: Switch on

This bit controls the switch BATVS1 on/off. But only when the ACS[3:0] bits value is "1000B", selecting the AN8 as the A/D converter input signal channel, and then set this BATVS1 bit high, can the switch be on. Otherwise this switch is always off.

Rev. 1.50 100 October 26, 2023

Bit 3 BATVS0: Internal divider resistor switch BATVS0 control

0: Switch off

1: Switch on

This bit controls the switch BATVS0 on/off. But only when the ACS[3:0] bits value is "1000B", selecting the AN8 as the A/D converter input signal channel and the BATVS1 bit is "0", turning off the BATVS1 switch, and then set this BATVS0 bit high, can the switch be on. Otherwise this switch is always off.

Bit 2 AN10SW: Internal analog switches AN10SW 0 and AN10SW 1 control

0: AN10SW\_0 on, AN10SW\_1 off 1: AN10SW 0 off, AN10SW 1 on

This bit controls the switches AN10SW\_0 and AN10SW\_1 on/off. But only when the ACS[3:0] bits value is "1010B", selecting the AN10 as the A/D converter input signal channel, is this bit setup valid. Otherwise these two switches are both off.

Bit 1 **OUVP0S1**: Internal bypass switch OUVP0S1 control

0: Switch off

1: Switch on

This bit controls the switch OUVP0S1 on/off. But only when the Pin-shared Function Control bits PAS1[1:0] value is "01B", selecting the AN10 pin function, and then set this OUVP0S1 bit high, can the switch be on. Otherwise this switch is always off.

Bit 0 **OUVP0S0**: Internal divider resistor switch OUVP0S0 control

0: Switch off

1: Switch on

This bit controls the switch OUVP0S0 on/off. But only when the Pin-shared Function Control bits PAS1[1:0] value is "01B", selecting the AN10 pin function and the OUVP0S1 bit is "0", turning off the OUVP0S1 switch, and then set this OUVP0S0 bit high, can the switch be on. Otherwise this switch is always off.

#### SWS1 Register

| Bit  | 7 | 6 | 5 | 4 | 3 | 2      | 1       | 0       |
|------|---|---|---|---|---|--------|---------|---------|
| Name | _ | _ | _ | _ | _ | AN11SW | OUVP1S1 | OUVP1S0 |
| R/W  | _ | _ | _ | _ | _ | R/W    | R/W     | R/W     |
| POR  | _ | _ | _ | _ | _ | 0      | 0       | 0       |

Bit 7~3 Unimplemented, read as "0"

Bit 2 AN11SW: Internal analog switches AN11SW 0 and AN11SW 1 control

0: AN11SW\_0 on, AN11SW\_1 off 1: AN11SW 0 off, AN11SW 1 on

This bit controls the switches AN11SW\_0 and AN11SW\_1 on/off. But only when the ACS[3:0] bits value is "1011B", selecting the AN11 as the A/D converter input signal channel, is this bit setup valid. Otherwise these two switches are both off.

Bit 1 **OUVP1S1**: Internal bypass switch OUVP1S1 control

0: Switch off

1: Switch on

This bit controls the switch OUVP1S1 on/off. But only when the Pin-shared Function Control bits PAS0[1:0] value is "01B", selecting the AN11 pin function, and then set this OUVP1S1 bit high, can the switch be on. Otherwise this switch is always off.

Bit 0 **OUVP1S0**: Internal divider resistor switch OUVP1S0 control

0: Switch off

1: Switch on

This bit controls the switch OUVP1S0 on/off. But only when the Pin-shared Function Control bits PAS0[1:0] value is "01B", selecting the AN11 pin function and the OUVP1S1 bit is "0", turning off the OUVP1S1 switch, and then set this OUVP1S0 bit high, can the switch be on. Otherwise this switch is always off.

## A/D Converter Operation

The START bit in the SADC0 register is used to start the A/D conversion. When the microcontroller sets this bit from low to high and then low again, an analog to digital conversion cycle will be initiated.

The ADBZ bit in the SADC0 register is used to indicate whether the analog to digital conversion process is in progress or not. This bit will be automatically set to 1 by the microcontroller after an A/D conversion is successfully initiated. When the A/D conversion is complete, the ADBZ will be cleared to 0. In addition, the corresponding A/D interrupt request flag will be set in the interrupt control register, and if the interrupts are enabled, an appropriate internal interrupt signal will be generated. This A/D internal interrupt signal will direct the program flow to the associated A/D internal interrupt address for processing. If the A/D internal interrupt is disabled, the microcontroller can poll the ADBZ bit in the SADC0 register to check whether it has been cleared as an alternative method of detecting the end of an A/D conversion cycle.

The clock source for the A/D converter, which originates from the system clock f<sub>SYS</sub>, can be chosen to be either f<sub>SYS</sub> or a subdivided version of f<sub>SYS</sub>. The division ratio value is determined by the SACKS2~SACKS0 bits in the SADC1 register. Although the A/D clock source is determined by the system clock f<sub>SYS</sub> and by bits SACKS2~SACKS0, there are some limitations on the maximum A/D clock source speed that can be selected. As the recommended range of permissible A/D clock period, t<sub>ADCK</sub>, is from 0.5μs to 10μs, care must be taken for system clock frequencies. For example, as the system clock operates at a frequency of 8MHz, the SACKS2~SACKS0 bits should not be set to 000, 001 or 111. Doing so will give A/D clock periods that are less than the minimum A/D clock period which may result in inaccurate A/D conversion values. Refer to the following table for examples, where values marked with an asterisk \* show where, depending upon the device, special care must be taken, as the values may be less than the specified minimum A/D Clock Period.

|                  |  | A/D Clock Period (t <sub>ADCK</sub> )        |  |  |   |   |   |                                   |  |  |  |  |
|------------------|--|--|--|--|---|---|---|-----------------------------------|--|--|--|--|
| f <sub>sys</sub> | SACKS[2:0]<br>= 000<br>(f <sub>SYS</sub> ) | SACKS[2:0]<br>= 001<br>(f <sub>SYS</sub> /2) | SACKS[2:0]<br>= 010<br>(f <sub>SYS</sub> /4) | SACKS[2:0]<br>= 011<br>(f <sub>SYS</sub> /8) | SACKS[2:0]<br>= 100<br>(f <sub>SYS</sub> /16) | SACKS[2:0]<br>= 101<br>(f <sub>SYS</sub> /32) | SACKS[2:0]<br>= 110<br>(f <sub>SYS</sub> /64) | SACKS[2:0]<br>= 111<br>(fsys/128) |  |  |  |  |

#### A/D Clock Period Examples

Controlling the power on/off function of the A/D converter circuitry is implemented using the ADCEN bit in the SADC0 register. This bit must be set high to power on the A/D converter. When the ADCEN bit is set high to power on the A/D converter internal circuitry a certain delay, as indicated in the timing diagram, must be allowed before an A/D conversion is initiated. Even if no pins are selected for use as A/D inputs, if the ADCEN bit is high, then some power will still be consumed. In power conscious applications it is therefore recommended that the ADCEN is cleared to reduce power consumption when the A/D converter function is not being used.

Rev. 1.50 October 26, 2023

## A/D Converter Reference Voltages

The reference voltage supply to the A/D converter can be supplied from the positive power supply pin, VDD, from an external reference source supplied on pin VREF or from the OPA 2.4V output voltage,  $V_R$ . The desired selection is made using the SAVRS[1:0] bits. When the SAVRS bit field is set to "00" or "11", the A/D converter reference voltage will come from the VDD pin. When the SAVRS bit field is set to "01", the A/D converter reference voltage will come from the VREF pin. Note that between the VREF pin and the  $V_{DD}$ , there is an internal 1k resistor which can be selected to connect or disconnect the  $V_{DD}$  using the SWS0 register VREFSW bit. When the SAVRS bit field is set to "10", the reference voltage is selected from the 2.4V OPA output voltage which is obtained by inputting the 1.2V bandgap voltage to the internal OPA with a gain of 2. So when the 2.4V  $V_R$  reference voltage is required, the ADVBGEN bit should be also set to enable the OPA function and the 1.2V Bandgap. The analog input values must not be allowed to exceed the value of the selected reference voltage.

## A/D Converter Input Signals

All the external A/D analog channel input pins are pin-shared with the I/O pins as well as other functions. The corresponding Pin-shared Function control register bit for each A/D external input pin determines whether the input pin are setup as A/D converter analog inputs or whether they have other functions. If the pin is setup to be as an A/D analog channel input, the original pin functions will be disabled. In this way, pins can be changed under program control to change their function between A/D inputs and other functions. All pull high resistors, which are setup through register programming, will be automatically disconnected if the pins are setup as A/D inputs. Note that it is not necessary to first setup the A/D pin as an input in the port control register to enable the A/D input as when the pin-shared function control bits enable an A/D input, the status of the port control register will be overridden.

There are two internal analog signals derived from the Over Current Protection 0 and Over Current Protection 1 analog output signals, which can be connected to the A/D converter as the analog input signal by configuring the ACS[3:0] bits. There are 12 external signal input channels, AN0~AN11. The ACS3~ACS0 bits can determine which external channel or internal signal is selected.

If the AN8, AN10 or AN11 input channel is selected, care must be taken that because each of them has a group of internal functional switched which are controlled by the SWS0 and SWS1 register bits, so the registers must also be correctly configured to obtain the required input signal.

## **Conversion Rate and Timing Diagram**

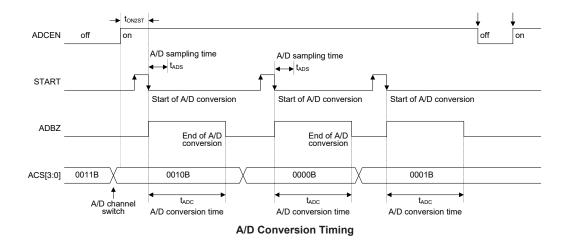

A complete A/D conversion contains two parts, data sampling and data conversion. The data sampling which is defined as t<sub>ADS</sub> takes 4 A/D clock periods and the data conversion takes 12 A/D clock periods. Therefore a total of 16 A/D clock periods for an external input A/D conversion which is defined as t<sub>ADC</sub> are necessary.

Maximum single A/D conversion rate =  $1/(A/D \text{ clock period} \times 16)$ 

The accompanying diagram shows graphically the various stages involved in an analog to digital conversion process and its associated timing. After an A/D conversion process has been initiated by the application program, the microcontroller internal hardware will begin to carry out the conversion, during which time the program can continue with other functions. The time taken for the A/D conversion is 16 taddk where taddk is equal to the A/D clock period.

Rev. 1.50 103 October 26, 2023

# Summary of A/D Conversion Steps

The following summarises the individual steps that should be executed in order to implement an A/D conversion process.

• Step 1

Select the required A/D conversion clock by correctly programming bits SACKS2~SACKS0 in the SADC1 register.

• Step 2

Enable the A/D by setting the ADCEN bit high in the SADC0 register.

Step 3

Select which signal is to be connected to the internal A/D converter by correctly configuring the ACS3~ACS0 bits.

• Step 4

Select the reference voltage source by configuring the SAVRS1~SAVRS0 bits in the SADC1 register.

• Step 5

Select A/D converter output data format by setting the ADRFS bit in the SADC0 register.

• Step 6

If A/D conversion interrupt is used, the interrupt control registers must be correctly configured to ensure the A/D interrupt function is active. As the A/D Converter interrupt is contained within a Multi-function interrupt, the associated multi-function interrupt enable bit, MFnE, the master interrupt control bit, EMI, and the A/D conversion interrupt control bit, ADE, must all be set high in advance.

• Step 7

The A/D conversion procedure can now be initialized by setting the START bit from low to high and then low again.

• Step 8

If A/D conversion is in progress, the ADBZ flag will be high. After the A/D conversion process is completed, the ADBZ flag will go low and then the output data can be read from SADOH and SADOL registers.

If A/D Converter interrupt is enabled and the stack is not full, data can be acquired by interrupt service program. Another way to get A/D output data is to polling ADBZ flag.

Note: When checking for the end of the conversion process, if the method of polling the ADBZ bit in the SADC0 register is used, the interrupt enable step above can be omitted.

Rev. 1.50 104 October 26, 2023

## **Programming Considerations**

During microcontroller operations where the A/D converter is not being used, the A/D internal circuitry can be switched off to reduce power consumption, by clearing bit ADCEN to 0 in the SADC0 register. When this happens, the internal A/D converter circuits will not consume power irrespective of what analog voltage is applied to their input lines. If the A/D converter input lines are used as normal I/Os, then care must be taken as if the input voltage is not at a valid logic level, then this may lead to some increase in power consumption.

#### A/D Conversion Function

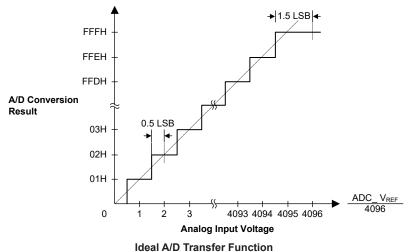

As the devices contain a 12-bit A/D converter, its full-scale converted digitised value is equal to FFFH. Since the full-scale analog input value is equal to the A/D Converter reference voltage ADC\_ $V_{REF}$  which can be selected from  $V_{DD}$ , VREF Pin input or OPA output  $V_R$ , this gives a single bit analog input value of ADC\_ $V_{REF}$  divided by 4096.

1 LSB=(ADC 
$$V_{REF}$$
) ÷ 4096

The A/D Converter input voltage value can be calculated using the following equation:

A/D input voltage=A/D output digital value 
$$\times$$
 (ADC\_V<sub>REF</sub>)  $\div$  4096

The diagram shows the ideal transfer function between the analog input value and the digitised output value for the A/D converter. Except for the digitised zero value, the subsequent digitised values will change at a point 0.5 LSB below where they would change without the offset, and the last full scale digitised value will change at a point 1.5 LSB below the ADC\_ $V_{REF}$  level.

# A/D Conversion Programming Examples

The following two programming examples illustrate how to setup and implement an A/D conversion. In the first example, the method of polling the ADBZ bit in the SADC0 register is used to detect when the conversion cycle is complete, whereas in the second example, the A/D interrupt is used to determine when the conversion is complete.

## Example: using an ADBZ polling method to detect the end of conversion

```
; disable ADC interrupt
clr ADE
mov a,03H
mov SADC1,a
                  ; select f_{\text{SYS}}/8 as A/D clock
set ADCEN
mov a,01h
                  ; setup PDPS0 to configure pin ANO
mov PDPS0,a
mov a,20h
mov SADCO, a
                  ; enable and connect ANO channel to A/D converter
start conversion:
clr START
                  ; high pulse on start bit to initiate conversion
set START
                  ; reset A/D
clr START
                  ; start A/D
polling EOC:
                   ; poll the SADCO register ADBZ bit to detect end of A/D
sz ADBZ
conversion
jmp polling_EOC ; continue polling
                 ; read low byte conversion result value
mov a,SADOL
mov SADOL buffer,a ; save result to user defined register
mov a, SADOH ; read high byte conversion result value
mov SADOH buffer,a ; save result to user defined register
jmp start_conversion; start next A/D conversion
```

Rev. 1.50 October 26, 2023

### Example: using the interrupt method to detect the end of conversion

```
; disable ADC interrupt
clr ADE
mov a,03H
mov SADC1,a
             ; select f_{SYS}/8 as A/D clock
set ADCEN
mov a,01h
                   ; setup PDPS0 to configure pin ANO
mov PDPS0,a
mov a,20h
                   ; enable and connect ANO channel to A/D converter
mov SADCO, a
Start conversion:
clr START ; high pulse on START bit to initiate conversion
                   ; reset A/D
set START
clr START
                   ; start A/D
clr ADF
                   ; clear ADC interrupt request flag
clr MF1F
                   ; clear Multi-function interrupt 1 request flag
                   ; enable ADC interrupt
set MF1E
                   ; enable Multi-function interrupt 1
set EMI
                   ; enable global interrupt
; ADC interrupt service routine
ADC ISR:
mov acc stack,a ; save ACC to user defined memory
mov a, STATUS
mov status stack,a ; save STATUS to user defined memory
                  ; read low byte conversion result value
mov a, SADOL
mov SADOL_buffer,a ; save result to user defined register
mov a,SADOH ; read high byte conversion result value
mov SADOH buffer,a ; save result to user defined register
EXIT INT ISR:
mov a, status stack
mov STATUS,a ; restore STATUS from user defined memory
mov a,acc_stack ; restore ACC from user defined memory
reti

# **High Resolution PWM Generator with Auto-adjust Control**

The devices contain a multi feature fully integrated PWM Generator which has complimentary outputs for maximum application flexibility.

# **Functional Description**

The High Resolution 8-bit PWM circuits include a PWM generator circuit, a delay lock loop circuit and PWM complementary outputs with dead time insertion. The devices also provide the PWM duty adjusting control for high resolution PWM output.

Note: 1. "\*":means it is the internal signal name and not the Special Function Register bit.

DT1SEL[5:0] and DT2SEL[5:0] are calculated and selected automatically based on the DT[4:0].

DT1CK is the PWMnH DT reference signal

DT2CK is the PWMnL DT reference signal

DLLCK is the H.R\_PWM reference signal

2. H.R=High Resolution

H.R PWM Output Block Diagram (n=0 or 1)

#### **High Resolution PWM Registers**

The basic operation of the High Resolution PWM is controlled using several registers. A PWM period register, PWMnP, exists to store the desired 8-bit PWM period value. The PWM duty value is stored in an 8-bit PWMnD register. The PWMn function control, PWMn counter clock selection, DLL circuit and dead time duration is determined by the PWMnC register. The register DLLn is used for the DLL circuit phase selection. The DLLC register is used for the DLL circuit enable control and the losing lock protection control.

There are also some registers used for the auto adjust PWM function. The register ADJnC is to control the auto adjust function enable or disable, the PWMn duty adjust operation control and store the OUVPn comparator output status. The ADJnS register is to select the adjust steps when over voltage or under voltage condition occurs while the ADJnDT is to select the auto adjust function delay time after being triggered. The two register pairs of ADJnMAXH & ADJnMAXL and ADJnMINH & ADJnMINL are used to set the maximum and minimum duty data. The register

Rev. 1.50 108 October 26, 2023

pair of ADJnBH& ADJnBL is used to store the auto-adjust PWM buffer duty data. The remaining register of OUTPC0 is used for the PWMn output signals control.

| R/W  | R/W     | R/W   | _ | _ | _ | _ | _ | R/W    |
| POR  | 0       | 0     | _ | _ | _ | _ | _ | 0      |

Bit 7 DLLLKEN: DLL circuit Losing Lock protection function control

0: Disable 1: Enable

Note: When DLLLKEN=1 and DLL function is enabled, if a losing lock condition occurs, the DLLLKF bit is set high and the losing lock condition will be sovled by DLL automatically. While when DLLLKEN=0, the DLLLKF bit is always zero even if a losing lock condition occurs, and the DLL will not solve the condition.

Bit 6 DLLEN: DLL and Dead Time function control bit

0: DLL disabled and no dead time inserted

1: DLL enabled and the dead time inserted which is decided by DTn[4:0]

If this bit is cleared then the PWMnCK[1:0] bits can be set to  $00\sim11$  by software and the H.R\_PWMn=PWMn, no dead time is inserted. If set high, the hardware will set PWMnCK[1:0] be 00 which cannot be changed, the PWMn will be finely adjusted by the DLL and then output the High Resolution PWM output with dead time inserted.

Bit 5~1 Unimplemented, read as "0"

Bit 0 DLLLKF: DLL circuit losing lock flag

0: No losing lock condition occurs

1: Losing lock occurs

This bit can be cleared to zero by software, but can not be set high by software.

Note: When DLLLKEN=1 and DLL function is enabled, if no losing lock condition occurs, the DLLLKF bit is 0, if a losing lock condition occurs, the DLLLKF bit is set high which can only be cleared by software. If DLLLKEN=0, the DLLLKF bit is always zero.

## ADJnDT Register

| R/W  | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    | R/W    |
| POR  | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |

Bit 7~4 **OVPnS[3:0]**: OVPn auto adjust PWMn duty steps selection

0000: 0 step 0001: 1 step ...

1111: 15 steps

Bit 3~0 UVPnS[3:0]: UVPn auto adjust PWMn duty steps selection

0000: 0 step 0001: 1 step

1111: 15 steps

#### ADJnC Register

| Bit  | 7      | 6     | 5      | 4 | 3     | 2     | 1 | 0 |
|------|--------|-------|--------|---|-------|-------|---|---|
| Name | ADJnEN | ADJnV | ADJnSW | _ | OVPnL | UVPnL | _ | _ |
| R/W  | R/W    | R/W   | R/W    | _ | R     | R     | _ | _ |
| POR  | 0      | 0     | 0      |   | х     | х     | _ | _ |

Bit 7 ADJnEN: Auto Adjust PWM Duty Function control

0: Disable 1: Enable

Bit 6 ADJnV: Auto Adjust PWMn Duty action selection

0: OVPnL increase duty, UVPnL decrease duty 1: OVPnL decrease duty, UVPnL increase duty

Bit 5 ADJnSW: PWMn Duty adjustment by S/W auto adjust control

0: Disable, write into Buffer from PWMnD+DLLn registers by F/W

1: Enable, write into Buffer by auto adjust system

When the ADJnEN is cleared to zero, the auto adjust circuit is off, so this bit is always 0. When the ADJnEN bit is set high, the auto adjust circuit is on. Then if the OVPnL or UVPnL is 1, this bit will be set to 1 automatically to trigger the auto adjust system to control the duty. When the auto duty adjustment is completed and if want to set the PWMn duty by F/W, then it needs to switch the ADJnSW bit from 1 to 0. Note that only when the OVPnL and UVPnL bits are equal to 0, can the bit be change from 1 to 0 successfully.

Bit 4 Unimplemented, read as "0"

Bit 3 **OVPnL**: OVPn Comparator Output Status

0: Output low (no over voltage occurs)1: Output high (over voltage occurs)

Bit 2 UVPnL: UVPn Comparator Output Status

0: Output low (no under voltage occurs)1: Output high(over voltage occurs)

Bit 1~0 Unimplemented, read as "0"

#### **PWM Generator**

The PWM signal generator is driven by the HIRC clock and can generate PWMn signal, with a variable duty and period cycles by configuring the 8-bit PWMnP and PWMnD registers. The PWMn signal period is dependent upon the PWMn counter clock source which is set by the PWMnCK[1:0] bits in the PWMnC register and determined by the PWMnP register. The PWMn signal duty is determined by the PWMD register content.

After the DLLn, DTn[4:0], PWMnD and PWMnP register values are changed by software, then the new data will be updated by the F/W when the PWMn Counter is cleared to zero.

# **Delay Lock Loop**

DLL is an abbreviation for Delay Lock Loop. The DLL can generate 16 phase outputs within one HIRC clock period. The 16 phase outputs are used to fine tune the PWMn signal output. The PWMn clock is  $f_{\rm HIRC}$ , which means that the PWMn output duty resolution is  $1/f_{\rm HIRC}$ . The PWMn signal passes through the DLLn phase selection and PWMn control which is set by the DLLn[3:0] bits in the DLLn register circuit to output a fine-tuned PWMn signal, H.R\_PWMn with the PWMn duty resolution increased by 4 bits.

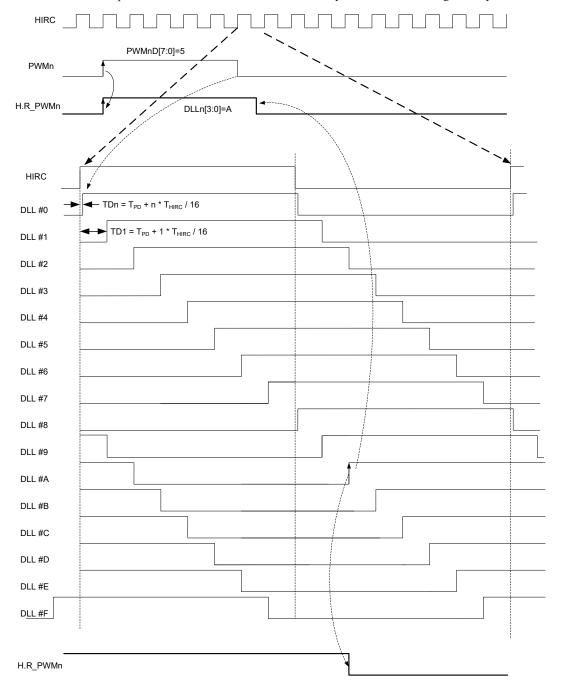

## **Losing Lock Protection**

The devices also provide the Losing lock protection circuit which can be enabled by the DLLLKEN bit. If the MCU is disturbed, a losing lock error that the phase time generated by the DLL is 1.5 times of the normal phase time may occur. If the DLLLKEN bit is high, the losing lock circuit is enabled

Rev. 1.50 114 October 26, 2023

and then the phase time will return normal in  $30\mu s$ . Additionally the flag bit DLLLKF which is 0 in normal operation will be set high to notify users that a losing lock error occurred. If the DLLLKEN bit is not set high, the Losing lock protection circuit is off. So after a losing lock condition occurs, the DLL phase time cannot return normal automatically and the DLLLKF flag is always 0.

## **Auto-adjust Circuit**

In order to increase the DC-DC response speed, the device provides an auto-adjust circuit together with the PWM generator. The following summarises the steps to implement the auto adjust function.

Step 1. Clear the ADJnEN bit to zero to turn off the auto-adjust circuit for initialization:

- Set the Maximum/Minimum Duty by programming the12-bit ADJnMAXH &ADJnMAXL and ADJnMINH &ADJnMINL registers. Note: 1<Min<(PWMnD+DLLn)<MAX</li>
- Configure the 6-bit ADJnDT register to set the delay time after every trigger.
- Set the ADJnV bit in the ADJnC register to select the duty adjust action (increase or decrease).
- Select the duty adjusting step (0~15) when OUVPn occurs by setting the ADJnS register.
- Set the OVPn and UVPn limited Voltage. Note: UVPn<Target Voltage<OVPn

## Step 2. PWMn Start:

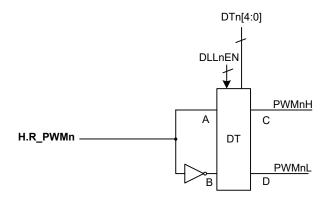

- PWMn initialization, including PWMnP and (PWMnD+DLLn) initialization
- Set the PWMnON bit high to enable the PWMn generator.
- Adjust the Duty after reading the OUVPn output, make sure the output voltage equal to the target voltage.
- Step 3. Set the ADJnEN bit high to enable the auto-adjust circuit, then the OVPnL/UVPnL level can trigger the auto adjustment function.
- Step 4. If an UVPn interrupt occurs, based on the UVPn and OCP comparator output, the firmware gives a delay time to determine the under-voltage condition is caused by increasing load instantaneously or by an external devices short circuit.
- Step 5. If an OVPn interrupt occurs, based on the OVPn comparator output, the firmware gives a delay time to determine the over-voltage condition is caused by decreasing load instantaneously or by an error on the feedback circuit.

#### **Dead-Time Insert**

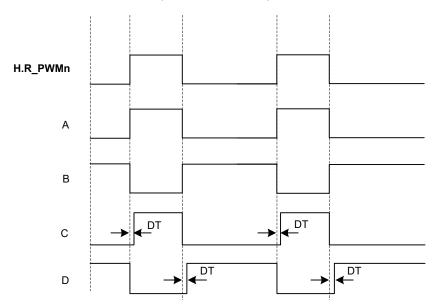

The devices provide a complementary output pair of signals which can be used as a PWMn driver signal. The signal is sourced from the High Resolution PWM output signal, 8-bit PWMn with DLL circuit. PWM output is an active high signal. By using the DLLnEN bit, the dead time generator will be enabled and a dead time, which is programmable using the DTn[4:0] bits in the PWMnC register, will be inserted to prevent excessive DC currents. The dead time will be inserted whenever the rising edge of the dead time generator input signal occurs.

Rev. 1.50 October 26, 2023

# Complementary PWM output (with dead time control)

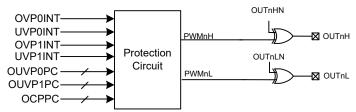

Note: C and D are the complementary PWMn control with dead time circuitry's output signals.

# **Protection and Inverting Control**

Although a dead time has been inserted into the H.R\_PWM complementary pair signals to prevent excessive DC current, these two signals may also be in an inactive state resulting from some unpredictable reasons, such as malfunctions or electrical noise. The devices provide a protection function to force the two signals to output inverting signals when the PWMnH or PWMnL signal is in an inactive state. The inverting control circuitry determines whether the signals are inverted or not using corresponding inverting control bit, OUTnHN or OUTnLN bit, in the OUTPC0 register.

The devices also include over current protection, over voltage protection and under voltage protection functions for the PWMn output signals which are described in the OCPn OCPPC register and OUVPn section OUVPnPC register. The PWM output OUT0H/OUT0L, OUT1H/OUT1L can be forced as inactive state controlled by OUT0HS/OUT0LS, OUT1HS/OUT1LS bits in the OUTPC0 register for either OCPn, OVPn or UVPn occurs. The OCPn/OVPn/UVPn also generates interrupt to inform MCU. Once OCPn/OVPn/UVPn disappears, the OUT0H/OUT0L, OUT1H/OUT1L will recover to send PWM output. Details about the current and voltage protection functions refer to the "Over Current Protection" and "Over/Under Voltage Protection" chapters.

## **Programming Considerations**

The following steps show the read and write procedures:

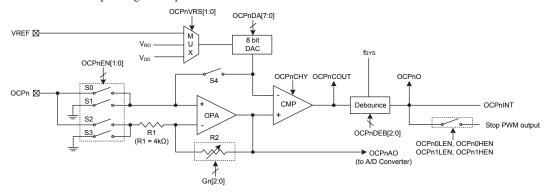

- · Writing Data to DLLn/PWMnD
  - Step 1. Write data to DLLn
    - Note that here data is only written to the 4-bit buffer.
  - Step 2. Write data to PWMnD
    - Here data is written directly to PWMnD register and simultaneously data is latched from the 4-bit buffer to the DLLn register.
- Reading Data from DLLn/PWMnD
  - Step 1. Read data from PWMnD
    - Here data is read directly from the PWMnD register and simultaneously data is latched from the DLLn register into the 4-bit buffer.
  - Step 2. Read data from DLLn
    - This step reads data from the 4-bit buffer.

Rev. 1.50 118 October 26, 2023

# **Over Current Protection**

The devices include the over current protection function which provides a protection mechanism for applications. To prevent the battery charge or load current from exceeding a specific level, the current on the OCPn pin is converted to a relevant voltage level according to the current value using the OCPn operational amplifier. It is then compared with a reference voltage generated by an 8-bit D/A converter. When an over current event occurs, an OCPn interrupt will be generated if the corresponding interrupt control is enabled.

Note: V<sub>RO</sub> is from the A/D Converter Unit gain buffer output and the OCPnAO can be selected as the A/D Converter input signals.

Over Current Protection Circuit (n=0 or 1)

## **Over Current Protection Operation**

The illustrated OCPn circuit is used to prevent the input current from exceeding a reference level. The current on the OCPn pin is converted to a voltage and then amplified by the OCPn operational amplifier with a programmable gain from 1 to 50 selected by the Gn2~Gn0 bits in the OCPnC1 register. This is known as a Programmable Gain Amplifier or PGA. This PGA can also be configured to operate in the non-inverting, inverting or input offset calibration mode determined by the OCPnEN1 and OCPnEN0 bits in the OCPnC0 register. After the current is converted and amplified to a specific voltage level, it will be compared with a reference voltage provided by an 8-bit DAC. The 8-bit DAC power can be V<sub>DD</sub>, V<sub>RO</sub> or V<sub>REF</sub>, selected by the OCPnVRS[1:0] bits in the OCPnC0 register. The comparator output, OCPnCOUT, will first be filtered with a certain de-bounce time period selected by the OCPnDEB2~OCPnDEB0 bits in the OCPnC1 register. Then a filtered OCPn digital comparator output, OCPnO, is obtained to indicate whether an over current condition occurs or not. The OCPnO bit will be set to 1 if an over current condition occurs. Otherwise, the OCPnO bit is zero. Once an over current event occurs, i.e., the converted voltage of the OCPn input current is greater than the reference voltage, the corresponding interrupt will be generated if the relevant interrupt control bit is enabled.

The devices provide over current protection control of the PWM output signals OUT0H/OUT0L, OUT1H/OUT1L which can be enabled by the corresponding OCPPC register bits. If the protection control is enabled, these signal status is controlled by the OUT0HS/OUT0LS, OUT1HS/OUT1LS bits in the OUTPC0 register when an over current protection condition occurs. The OCPn also generates an interrupt to inform the MCU. Once the over current condition is resolved the OUT0H/OUT0L, OUT1H/OUT1L outputs will recover and continue to generate PWM signals.

Details about the OUTnH and OUTnL signal polarity and output control when OCPn occurs is described in the OCPPC register description.

Rev. 1.50 119 October 26, 2023

## **Over Current Protection Control Registers**

Overall operation of the over current protection is controlled using several registers. One register is used to provide the reference voltages for the over current protection circuit. There are two registers used to cancel out the operational amplifier and comparator input offset. The two control registers are to control the OCPn function, D/A converter reference voltage select, PGA gain select, comparator de-bounce time together with the hysteresis function. The remaining register of OCPPC is used to control the whether the PWMn output signals OUT0H/OUT0L, OUT1H/OUT1L is forced into an inactive state when an OCPn condition occurs.

| Name | OCPnOOFM | OCPnORSP | OCPnOOF5 | OCPnOOF4 | OCPnOOF3 | OCPnOOF2 | OCPnOOF1 | OCPnOOF0 |
| R/W  | R/W      | R/W      | R/W      | R/W      | R/W      | R/W      | R/W      | R/W      |
| POR  | 0        | 0        | 1        | 0        | 0        | 0        | 0        | 0        |

Bit 7 OCPnOOFM: OCPn Operational Amplifier normal operation or input offset voltage cancellation mode selection

0: Normal operation, input offset calibration disabled

1: Input Offset Calibration Mode

This bit is used to control the OCPn operational amplifier input offset Calibration function. The OCPnEN1 and OCPnEN0 bits must first be set to "11" and then the OCPnOOFM bit must be set to 1 followed by the OCPnCOFM bit being cleared to 0, then the operational amplifier input offset Calibration mode will be enabled. Refer to the "Operational Amplifier Input Offset Calibration" section for the detailed offset Calibration procedures.

Bit 6 OCPnORSP: OCPn Operational Amplifier Input Offset Voltage Calibration Reference selection

0: Select negative input as the reference input

1: Select positive input as the reference input

Bit 5~0 **OCPnOOF[5:0]**: OCPn Operational Amplifier Input Offset Voltage Calibration value This 6-bit field is used to perform the operational amplifier input offset calibration operation and the value for the OCPn operational amplifier input offset calibration can be restored into this bit field. More detailed information is described in the "Operational Amplifier Input Offset Calibration" section.

#### OCPnCCAL Register

| Bit  | 7        | 6        | 5        | 4        | 3        | 2        | 1        | 0        |
|------|----------|----------|----------|----------|----------|----------|----------|----------|
| Name | OCPnCOUT | OCPnCOFM | OCPnCRSP | OCPnCOF4 | OCPnCOF3 | OCPnCOF2 | OCPnCOF1 | OCPnCOF0 |
| R/W  | R        | R/W      |
| POR  | 0        | 0        | 0        | 1        | 0        | 0        | 0        | 0        |

Bit 7 OCPnCOUT: OCP Comparator Output bit, positive logic (read only)

0: Positive input voltage < Negative input voltage

1: Positive input voltage > Negative input voltage

This bit is used to indicate whether the positive input voltage is greater than the negative input voltage when the OCPn operates in the input offset Calibration mode. If the OCPnCOUT is set to 1, the positive input voltage is greater than the negative input voltage. Otherwise, the positive input voltage is less than the negative input voltage.

Bit 6 OCPnCOFM: OCPn Comparator normal operation or input offset calibration mode selection

0: Normal operation, input offset calibration mode disabled

1: Input Offset Calibration Mode Enabled

This bit is used to control the OCPn comparator input offset Calibration function. The OCPnEN1 and OCPnEN0 bits must first be set to "11" and then the OCPnCOFM bit must be set to 1 followed by the OCPnOOFM bit being cleared to 0, then the comparator input offset calibration mode will be enabled. Refer to the "Comparator Input Offset Calibration" section for the detailed offset calibration procedures.

Bit 5 OCPnCRSP: OCPn Comparator Input Offset Calibration Reference Input selection

0: Select negative input as the reference input

1: Select positive input as the reference input

Bit 4~0 **OCPnCOF4~OCPnCOF0**: OCPn Comparator Input Offset Calibration value

This 5-bit field is used to perform the comparator input offset calibration operation and the value for the OCPn comparator input offset calibration can be restored into this bit field. More detailed information is described in the "Comparator Input Offset Calibration" section.

#### OCPPC Register

| Bit  | 7        | 6        | 5        | 4        | 3        | 2        | 1        | 0        |
|------|----------|----------|----------|----------|----------|----------|----------|----------|
| Name | OCP11LEN | OCP11HEN | OCP10LEN | OCP10HEN | OCP01LEN | OCP01HEN | OCP00LEN | OCP00HEN |
| R/W  | R/W      | R/W      | R/W      | R/W      | R/W      | R/W      | R/W      | R/W      |
| POR  | 0        | 0        | 0        | 0        | 0        | 0        | 0        | 0        |

Bit 7 OCP11LEN: OUT1L Over Current Protection 1 Enable control

0: Disable 1: Enable

This bit is used to control the OUT1L signal output when an over current 1 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT1L output will not be affected when OCP1 occurs. If set this bit high, the function is enabled. This means when an OCP1 condition occurs the OUT1L status is controlled by the OUT1LS bit in the OUTPC0 register.

Rev. 1.50 122 October 26, 2023

Bit 6 OCP11HEN: OUT1H Over Current Protection 1 Enable control

0: Disable 1: Enable

This bit is used to control the OUT1H signal output when an over current 1 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT1H output will not be affected when OCP1 occurs. If set this bit high, the function is enabled. This means when an OCP1 condition occurs the OUT1H status is controlled by the OUT1HS bit in the OUTPC0 register.

Bit 5 OCP10LEN: OUT0L Over Current Protection 1 Enable control

0: Disable

1: Enable

This bit is used to control the OUT0L signal output when an over current 1 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0L output will not be affected when OCP1 occurs. If set this bit high, the function is enabled. This means when an OCP1 condition occurs the OUT0L status is controlled by the OUT0LS bit in the OUTPC0 register.

Bit 4 OCP10HEN: OUT0H Over Current Protection 1 Enable control

0: Disable

1: Enable

This bit is used to control the OUT0H signal output when an over current 1 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0H output will not be affected when OCP1 occurs. If set this bit high, the function is enabled. This means when an OCP1 condition occurs the OUT0H status is controlled by the OUT0HS bit in the OUTPC0 register.

Bit 3 OCP01LEN: OUT1L Over Current Protection 0 Enable control

0: Disable

1: Enable

This bit is used to control the OUT1L signal output when an over current 0 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT1L output will not be affected when OCP0 occurs. If set this bit high, the function is enabled. This means when an OCP0 condition occurs the OUT1L status is controlled by the OUT1LS bit in the OUTPC0 register.

Bit 2 OCP01HEN: OUT1H Over Current Protection 0 Enable control

0: Disable

1: Enable

This bit is used to control the OUT1H signal output when an over current 0 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT1H output will not be affected when OCP0 occurs. If set this bit high, the function is enabled. This means when an OCP0 condition occurs the OUT1H status is controlled by the OUT1HS bit in the OUTPC0 register.

Bit 1 OCP00LEN: OUT0L Over Current Protection 0 Enable control

0: Disable

1: Enable

This bit is used to control the OUT0L signal output when an over current 0 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0L output will not be affected when OCP0 occurs. If set this bit high, the function is enabled. This means when an OCP0 condition occurs the OUT0L status is controlled by the OUT0LS bit in the OUTPC0 register.

Bit 0 OCP00HEN: OUT0H Over Current Protection 0 Enable control

0: Disable

1: Enable

This bit is used to control the OUT0H signal output when an over current 0 condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0H output will not be affected when OCP0 occurs. If set this bit high, the function is enabled. This means when an OCP0 condition occurs the OUT0H status is controlled by the OUT0HS bit in the OUTPC0 register.

## **Input Voltage Range**

Together with different PGA operating modes, the input voltage on the OCPn pin can be positive or negative for flexible operation. The PGA output for the positive or negative input voltage is calculated based on different formulas and described by the following.

• For input voltages  $V_{\rm IN}$  > 0, the PGA operates in the non-inverting mode and the PGA output is obtained using the formula below:

$$V_{OUT} = (1 + \frac{R_2}{R_1}) \times V_{IN}$$

• When the PGA operates in the non-inverting mode by setting the OCPnEN[1:0] to "01" with unity gain select by setting the Gn[2:0] to "000", the PGA will act as a unit-gain buffer whose output is equal to  $V_{\rm IN}$ .

$$V_{OUT} = V_{IN}$$

For input voltages 0 >V<sub>IN</sub> >-0.2V, the PGA operates in the inverting mode and the PGA output
is obtained using the formula below. Note that if the input voltage is negative, it cannot be lower
than -0.2V which will result in current leakage.

$$V_{OUT} = \frac{R_2}{R_1} \times V_{IN}$$

## **OCPn OPA and Comparator Offset Calibration**

The OCPn circuit has four operating modes controlled by OCPnEN[1:0], one of them is calibration mode. In calibration mode, Operational amplifier and comparator offset can be calibrated.

## **Operational Amplifier Input Offset Calibration**

- Step 1. Set OCPnEN[1:0]=11, OCPnOOFM=1 and OCPnCOFM=0, the OCPn will operate in the operational amplifier input offset Calibration mode.
- Step 2. Set OCPnOOF[5:0]=000000 and then read the OCPnCOUT bit.
- Step 3. Increase the OCPnOOF[5:0] value by 1 and then read the OCPnCOUT bit.

If the OCPnCOUT bit state has not changed, then repeat Step 3 until the OCPnCOUT bit state has changed.

If the OCPnCOUT bit state has changed, record the OCPnOOF value as  $V_{\text{OOS1}}$  and then go to Step 4.

- Step 4. Set OCPnOOF[5:0]=111111 and read the OCPnCOUT bit.
- Step 5. Decrease the OCPnOOF[5:0] value by 1 and then read the OCPnCOUT bit.

If the OCPnCOUT bit state has not changed, then repeat Step 5 until the OCPnCOUT bit state has changed.

If the OCPnCOUT bit state has changed, record the OCPnOOF value as  $V_{\text{OOS2}}$  and then go to Step 6.

Step 6. Restore the operational amplifier input offset calibration value  $V_{\rm oos}$  into the OCPnOOF[5:0] bit field. The offset Calibration procedure is now finished.

Where 
$$V_{OOS} = \frac{V_{OOS1} + V_{OOS2}}{2}$$

Rev. 1.50 124 October 26, 2023

#### **Comparator Input Offset Calibration**

- Step 1. Set OCPnEN[1:0]=11, OCPnCOFM=1 and OCPnOOFM=0, the OCPn is now in the comparator input offset calibration mode. S4 is on (S4 is used for calibration mode, in normal mode operation, it is off).
- Step 2. Set OCPnCOF[4:0]=00000 and read the OCPnCOUT bit.
- Step 3. Increase the OCPnCOF[4:0] value by 1 and then read the OCPnCOUT bit.

  If the OCPnCOUT bit state has not changed, then repeat Step 3 until the OCPnCOUT bit state has changed.
  - If the OCPnCOUT bit state has changed, record the OCPnCOF value as  $V_{\rm COS1}$  and then go to Step 4.
- Step 4. Set OCPnCOF[4:0]=11111 and then read the OCPnCOUT bit.
- Step 5. Decrease the OCPnCOF[4:0] value by 1 and then read the OCPnCOUT bit.

  If the OCPnCOUT bit state has not changed, then repeat Step 5 until the OCPnCOUT bit state has changed.

  If the OCPnCOUT bit state has changed, record the OCPnCOE value as Vacce and then go to
  - If the OCPnCOUT bit state has changed, record the OCPnCOF value as  $V_{\text{COS2}}$  and then go to Step 6.
- Step 6. Restore the comparator input offset calibration value  $V_{\text{COS}}$  into the OCPnCOF[4:0] bit field. The offset Calibration procedure is now finished.

Where 
$$V_{COS} = \frac{V_{COS1} + V_{COS2}}{2}$$

Rev. 1.50 October 26, 2023

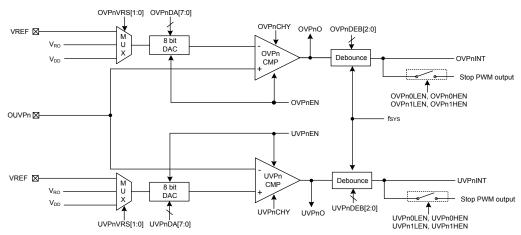

# **Over/Under Voltage Protection**

The devices include the internal over/under voltage protection (OUVP) function which can be used for the application of battery charge/discharge.

# **OUVP Circuit Operation**

The OUVP circuit is built-in with the Over Voltage Protection (OVPn) and the Under Voltage Protection (UVPn) functions.

Note: V<sub>RO</sub> is from the A/D Converter Unit gain buffer

Over/Under Voltage Protection Block Diagram (n=0 or 1)

#### **Over Voltage Protection Function**

To prevent the output voltage from exceeding the specific voltage level, the OVPn input voltage is compared with a reference voltage generated by an 8-bit D/A converter. The 8-bit DAC reference input signal range can come from  $V_{DD}$ ,  $V_{RO}$ , or external VREF pin which is selected by the OVPnVRS[1:0] bits. Once the OVPn input voltage is greater than the reference voltage, the OVPnO will change from "0" to "1". The OVPnINT is the de-bounce version of OVPnO and used to indicate that the source voltage coming from OUVPn input is over the specification or not. OVPnO is defined as OVPn output and OVPnINT is OVPn interrupt trigger. The comparator of the OVPn also has a hysteresis function controlled by OVPnCHY bit.

#### **Under Voltage Protection Function**

To prevent the output voltage from being less than the specific voltage, the UVPn input voltage is compared with a reference voltage generated by an 8-bit D/A converter. The 8-bit DAC reference input signal range can come from  $V_{DD}$ ,  $V_{RO}$ , or external VREF pin which is selected by the UVPnVRS[1:0] bits. Once the UVPn input voltage is lower than the reference voltage, the UVPnO will change from "0" to "1". The UVPnINT is the de-bounce version of UVPnO and used to indicate that the source voltage coming from the OUVPn input is under the specification or not. UVPnO is defined as UVPn output and UVPnINT is UVPn interrupt trigger. The comparator of the UVPn also has a hysteresis function controlled by UVPnCHY bit.

The devices provide over and under voltage protection control of the PWM output signals OUT0H/OUT0L, OUT1H/OUT1L which can be enabled by the corresponding OUVPnPC register bits. If the protection control is enabled, these signal status is controlled by the OUT0HS/OUT0LS, OUT1HS/OUT1LS bits in the OUTPC0 register for an over voltage or under voltage condition occurs. The OVPn/UVPn also generates interrupt to inform MCU. Once the OVPn/UVPn condition disappears, the OUT0H/OUT0L, OUT1H/OUT1L outputs will continue to generate PWM signals.

Details about the OUTnH and OUTnL signal polarity and output control when OVPn or UVPn occurs is described in the OUVPnPC register description.

Rev. 1.50 126 October 26, 2023

# **OUVPn Register Description**

The overall operation of the voltage protection and under voltage protection is controlled using several registers.

| Register |          |          |          | В        | Bit      |          |          |          |

Bit 7~0 **D[7:0]**: Data bits for UVPn DAC output control UVPn DAC Output=(UVPn DAC reference voltage) × (UVPnDA[7:0])/256

## OUVPnC0 Register

| Bit  | 7 | 6 | 5      | 4       | 3        | 2        | 1        | 0        |
|------|---|---|--------|---------|----------|----------|----------|----------|
| Name | _ | _ | OVPnEN | OVPnCHY | OVPnVRS1 | OVPnVRS0 | OVPnDEB1 | OVPnDEB0 |
| R/W  | _ | _ | R/W    | R/W     | R/W      | R/W      | R/W      | R/W      |
| POR  | _ | _ | 0      | 0       | 0        | 0        | 0        | 0        |

Bit 7~6 Unimplemented, read as "0"

Bit 5 **OVPnEN**: Over Voltage Protection n function Enable control

0: Disable

1: Enable

If the OVPnEN bit is cleared to 0, the over voltage protection n function is disabled and no power will be consumed. This results in the comparator and D/A converter of OVPn all being switched off.

Bit 4 **OVPnCHY**: Over Voltage Protection n Comparator Hysteresis Enable control

0: Disable

1: Enable

Bit 3~2 **OVPnVRS[1:0]**: OVPn DAC reference voltage selection

00: From  $V_{\text{DD}}$ 

01: From external VREF pin 10: From internal  $V_{RO}$ 

11: From V<sub>DD</sub>

Note: when seting these bits to "10" to select the  $V_{RO}$  as the OVPn DAC reference voltage, care must be taken that as the  $V_{RO}$  signal is from the Unit gain buffer output, so the Unit gain buffer must first be enabled by setting the ADVBGEN bit high.

Bit 1~0 **OVPnDEB[1:0]**: Over Voltage Protection n comparator debounce time selection

00: No debounce 01: (7~8) × 1/f<sub>SYS</sub> 10: (15~16) × 1/f<sub>SYS</sub> 11: (31~32) × 1/f<sub>SYS</sub>

#### • OUVPnC1 Register

| Bit  | 7 | 6 | 5      | 4       | 3        | 2        | 1        | 0        |
|------|---|---|--------|---------|----------|----------|----------|----------|

| POR  | _ | _ | 0      | 0       | 0        | 0        | 0        | 0        |

Bit 7~6 Unimplemented, read as "0"

Bit 5 **UVPnEN**: Under Voltage Protection n function Enable control

0: Disable 1: Enable

If the UVPnEN bit is cleared to 0, the under voltage protection n function is disabled and no power will be consumed. This results in the comparator and D/A converter of UVPn all being switched off.

Bit 4 UVPnCHY: Under Voltage Protection n Comparator Hysteresis Enable control

0: Disable 1: Enable

Bit 3~2 UVPnVRS[1:0]: UVPn DAC reference voltage selection

00: From  $V_{\text{DD}}$ 

01: From external VREF pin

10: From internal V<sub>RO</sub>

11: From  $V_{\text{DD}}$ 

Note: when seting these bits to "10" to select the  $V_{RO}$  as the UVPn DAC reference voltage, care must be taken that as the  $V_{RO}$  signal is from the Unit gain buffer output, so the Unit gain buffer must first be enabled by setting the ADVBGEN bit high.

Bit 1~0 UVPnDEB[1:0]: Under Voltage Protection n comparator debounce time selection

00: No debounce 01: (7~8) × 1/f<sub>SYS</sub> 10: (15~16) × 1/f<sub>SYS</sub> 11: (31~32) × 1/f<sub>SYS</sub>

# • OUVPnC2 Register

Bit 7 UVPnO: UVPn comparator output bit

0: Positive input voltage < negative input voltage

1: Positive input voltage > negative input voltage

Bit 6 UVPnCOFM: UVPn comparator normal operation or input offset voltage cancellation mode selection bit

0: Normal operation

1: Input offset voltage calibration mode

Bit 5 UVPnCRS: UVPn comparator input offset voltage calibration reference selection bit

0: Input reference voltage comes from negative input

1: Input reference voltage comes from positive input

This bit is used to select that the reference input voltage comes from the UVPn D/A converter or external input. Note that this bit is only available when the UVPn comparator input offset voltage calibration mode is selected by setting the UVPnCOFM bit to 1.

Bit 4~0 UVPnCOF[4:0]: UVPn comparator input offset voltage calibration control bits

## OUVPnPC Register

| Bit  | 7        | 6        | 5        | 4        | 3        | 2        | 1        | 0        |

| POR  | 0        | 0        | 0        | 0        | 0        | 0        | 0        | 0        |

Bit 7 UVPn1LEN: OUT1L Under Voltage Protection n Enable control

0: Disable

1: Enable

This bit is used to control the OUT1L signal output when the under voltage protection condition occurs. If this bit is cleared to 0 the function is disabled. This means the OUT1L output will not be affected when UVPn occurs. If set this bit high, the function is enabled. This means when an UVPn condition occurs the OUT1L status is controlled by the OUT1LS bit in the OUTPC0 register.

Bit 6 UVPn1HEN: OUT1H Under Voltage Protection n Enable control

0: Disable

1: Enable

This bit is used to control the OUT1H signal output when the under voltage protection condition occurs. If clear this bit to 0, the function is disabled. This means the OUT1H output will not be affected when UVPn occurs. If set this bit high, the function is enabled. This means when an UVPn condition occurs the OUT1H status is controlled by the OUT1HS bit in the OUTPC0 register.

Bit 5 UVPn0LEN: OUT0L Under Voltage Protection n Enable control

0: Disable

1: Enable

This bit is used to control the OUT0L signal output when the under voltage protection condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0L output will not be affected when UVPn occurs. If set this bit high, the function is

enabled. This means when an UVPn condition occurs the OUT0L status is controlled by the OUT0LS bit in the OUTPC0 register.

Bit 4 **UVPn0HEN**: OUT0H Under Voltage Protection n Enable control

0: Disable 1: Enable

This bit is used to control the OUT0H signal output when the under voltage protection condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0H output will not be affected when UVPn occurs. If set this bit high, the function is enabled. This means when an UVPn condition occurs the OUT0H status is controlled by the OUT0HS bit in the OUTPC0 register.

Bit 3 **OVPn1LEN**: OUT1L Over Voltage Protection n Enable control

0: Disable 1: Enable

This bit is used to control the OUT1L signal output when the over voltage protection condition occurs. If clear this bit to 0, the function is disabled. This means the OUT1L output will not be affected when OVPn occurs. If set this bit high, the function is enabled. This means when an OVPn condition occurs the OUT1L status is controlled by the OUT1LS bit in the OUTPC0 register.

Bit 2 **OVPn1HEN**: OUT1H Over Voltage Protection n Enable control

0: Disable 1: Enable

This bit is used to control the OUT1H signal output when the over voltage protection condition occurs. If clear this bit to 0, the function is disabled. This means the OUT1H output will not be affected when OVPn occurs. If set this bit high, the function is enabled. This means when an OVPn condition occurs the OUT1H status is controlled by the OUT1HS bit in the OUTPC0 register.

Bit 1 **OVPn0LEN**: OUT0L Over Voltage Protection n Enable control

0: Disable 1: Enable

This bit is used to control the OUT0L signal output when the over voltage protection condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0L output will not be affected when OVPn occurs. If set this bit high, the function is enabled. This means when an OVPn condition occurs the OUT0L status is controlled by the OUT0LS bit in the OUTPC0 register.

Bit 0 **OVPn0HEN**: OUT0H Over Voltage Protection n Enable control

0: Disable 1: Enable

This bit is used to control the OUT0H signal output when the over voltage protection condition occurs. If clear this bit to 0, the function is disabled. This means the OUT0H output will not be affected when OVPn occurs. If set this bit high, the function is enabled. This means when an OVPn condition occurs the OUT0H status is controlled by the OUT0HS bit in the OUTPC0 register.

# **OVPn and UVPn Comparator Offset Calibration**

The OVPn and UVPn circuits provide comparator offset calibration function. Before offset calibration, the hysteresis voltage should be zero by clearing the OVPnCHY or UVPnCHY bit to zero. As the OUVPn input pins are pin-shared with other functions, the OUVPn pin function must first be setup as comparator input using the corresponding pin-shared function selection register bits. The following content are the steps for the OVPn or UVPn comparator calibration.

## **OVPn Comparator Calibration:**

Step1: Set OVPnCOFM=1, OVPnCRS=1, comparator is now under offset calibration mode. To make sure V<sub>OS</sub> as minimize as possible after calibration, the input reference voltage in calibration should be the same as input DC operating voltage in normal mode operation.

Rev. 1.50 130 October 26, 2023

Step2: Set OVPnCOF[4:0]=00000 and then read the OVPnO bit

Step3: Increase the OVPnCOF[4:0] by 1 and then read the OVPnO bit.

If the OVPnO bit state has not changed, then repeat Step 3 until the OVPnO bit state has changed.

If the OVPnO bit state has changed, record the OVPnCOF[4:0] value as  $V_{\rm OS1}$  and then go to Step 4.

Step4: Set OVPnCOF[4:0]=11111 and then read the OVPnO bit

Step5: Decrease the OVPnCOF[4:0] value by 1 and then read the OVPnO bit.

If the OVPnO bit state has not changed, then repeat Step 5 until the OVPnO bit state has changed.

If the OVPnO bit state has changed, record the OVPnCOF[4:0] value as  $V_{\rm OS2}$  and then go to Step 6.

Step6: Restore the  $V_{OS} = \frac{V_{OS1} + V_{OS2}}{2}$  to OVPnCOF[4:0] bit field, the calibration procedure is now finished.

If  $(V_{OS1} + V_{OS2}) / 2$  is not integral, discard the decimal.

Residue 
$$V_{OS}=V_{OUT} - V_{IN}$$
 (1)

#### **UVPn Comparator Calibration:**

Step1: Set UVPnCOFM=1, UVPnCRS=1, comparator is now under offset calibration mode. To make sure Vos as minimize as possible after calibration, the input reference voltage in calibration should be the same as input DC operating voltage in normal mode operation.

Step2: Set UVPnCOF[4:0]=00000 and then read the UVPnO bit

Step3: Increase the UVPnCOF[4:0] by 1 and then read the UVPnO bit.

If the UVPnO bit state has not changed, then repeat Step 3 until the UVPnO bit state has changed.

If the UVPnO bit state has changed, record the UVPnCOF[4:0] value as  $V_{\rm OS1}$  and then go to Step 4.

Step4: Set UVPnCOF[4:0]=11111 and then read the UVPnO bit

Step5: Decrease the UVPnCOF[4:0] value by 1 and then read the UVPnO bit.

If the UVPnO bit state has not changed, then repeat Step 5 until the UVPnO bit state has changed.

If the UVPnO bit state has changed, record the UVPnCOF[4:0] value as  $V_{\text{OS2}}$  and then go to Step 6.

Step6: Restore the  $V_{OS} = \frac{V_{OS1} + V_{OS2}}{2}$  to UVPnCOF[4:0] bit field, the calibration procedure is now finished.

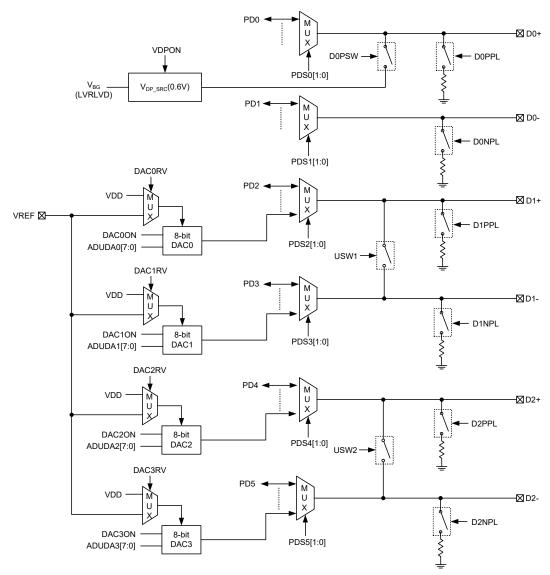

If  $(V_{OS1} + V_{OS2}) / 2$  is not integral, discard the decimal.

Residue 
$$V_{OS}=V_{OUT} - V_{IN}$$

# **USB Auto Detection**

The devices include three USB ports named D0+/D0-, D1+/D1- and D2+/D2- to implement the Charge/Discharge Devices Auto Detection function. Users can distinguish the device connected to the USB ports is a dedicated charger, portable device, general USB interface or charging device with USB interface by monitoring the voltage and current of the connected USB lines.

**USB Auto Detection Block Diagram** 

#### D0+/D0- for Auto Detection

The D0+ line can output a voltage,  $V_{DP\_SRC}$ , with a value of 0.6V, which is enabled by setting the VDPON bit of ADUC1 register and switched on by setting the D0PS bit in the ADUC1 register. But it needs to note that only when the D0+ pin is set as an analog or digital input pin by writing the Pin-shared Function register bit a correct data, and then set the D0PS bit high, can the switch be on. When this port is connected to a dedicated charger, the 0.6V voltage can be output on the D0+ line. The D0+ and D0- lines are pin-shared with normal I/O function and A/D function determined by the

Rev. 1.50 132 October 26, 2023

PDS0[1:0] and PDS1[1:0] bits respectively in the PDPS0 register. Both the D0+ and D0- lines are internally connected a pull low resistor to VSS which are controlled by the D0NPL and D0PPL bits in the ADUC2 register.

#### D1+/D1- and D2+/D2- for Auto Detection

There four 8-bit D/A Converters, DACn, which is enabled by the DACnON bits in the ADUC0 register. The D/A Converter output signal is controlled by the ADUDAn register value and the reference voltage which is selected by the DACnRV bit in the ADUC0 register. There is an analog switch connected between the D1+ and D1- lines, which is controlled by the USW1 bit. Similarly, there is an analog switch connected between the D2+ and D2- lines, which is controlled by the USW2 bit. But it needs to note that only when one of the D1+ and D1- or D2+ and D2- pins is in the analog or digital input type by setting the Pin-shared Function register, and then set the USW1or USW2 bit high, can the switch be on. The D1+ /D1- and D2+ /D2- lines are individually connected a pull low resistor respectively to VSS which are controlled by the D1NPL/D1PPL and D2NPL/D2PPL bits in the ADUC2 register.

## **USB Auto Detection Registers**

Overall operation of the USB auto detection function is controlled using several registers.

| Register |        |        |        | В      | it     |        |        |        |

# Serial Interface Module - SIM

The devices contain a Serial Interface Module, which includes both the four line SPI interface and the two line I<sup>2</sup>C interface types, to allow an easy method of communication with external peripheral hardware. Having relatively simple communication protocols, these serial interface types allow the microcontroller to interface to external SPI or I<sup>2</sup>C based hardware such as sensors, Flash memory, etc. As both interface types share the same pins and registers, the choice of whether the SPI or I<sup>2</sup>C type is used is made using the SIM operating mode control bits, named SIM2~SIM0, in the SIMC0 register. These pull-high resistors of the SIM pin-shared I/O pins are selected using pull-high control registers when the SIM function is enabled and the corresponding pins are used as SIM input pins.

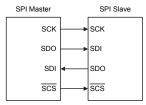

#### **SPI Interface**

The SPI interface is often used to communicate with external peripheral devices such as sensors, Flash memory devices etc. Originally developed by Motorola, the four line SPI interface is a synchronous serial data interface that has a relatively simple communication protocol simplifying the programming requirements when communicating with external hardware devices.

The communication is full duplex and operates as a slave/master type, where the device can be either master or slave. Although the SPI interface specification can control multiple slave devices from a single master, but this device is provided only one  $\overline{SCS}$  pin. If the master needs to control multiple slave devices from a single master, the master can use I/O pin to select the slave devices.

#### **SPI Interface Operation**

The SPI interface is a full duplex synchronous serial data link. It is a four line interface with pin names SDI, SDO, SCK and  $\overline{SCS}$ . Pins SDI and SDO are the Serial Data Input and Serial Data Output lines; SCK is the Serial Clock line and  $\overline{SCS}$  is the Slave Select line. As the SPI interface pins are pin-shared with normal I/O pins and with the I<sup>2</sup>C function pins, the SPI interface must first be enabled by setting the correct bits in the SIMC0 and SIMC2 registers. The SPI can be disabled or enabled using the SIMEN bit in the SIMC0 register. Communication between devices connected to the SPI interface is carried out in a slave/master mode with all data transfer initiations being implemented by the master. The Master also controls the clock signal. As the device only contains a single  $\overline{SCS}$  pin only one slave device can be utilized. The  $\overline{SCS}$  pin is controlled by software, set CSEN bit to "1" to enable  $\overline{SCS}$  pin function, set CSEN bit to "0" the  $\overline{SCS}$  pin will be floating state.

SPI Master/Slave Connection

Note: For the HT45F5N, the SDO and SDI pins are not bounded to the external package.

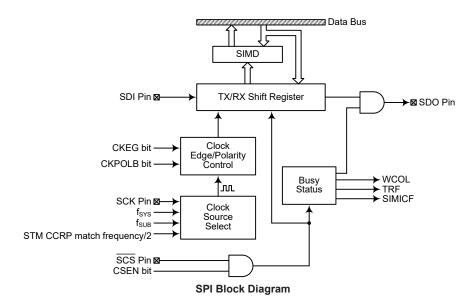

The SPI function in the device offers the following features:

- Full duplex synchronous data transfer
- · Both Master and Slave modes
- · LSB first or MSB first data transmission modes
- Transmission complete flag
- · Rising or falling active clock edge

The status of the SPI interface pins is determined by a number of factors such as whether the device is in the master or slave mode and upon the condition of certain control bits such as CSEN and SIMEN.

Rev. 1.50 136 October 26, 2023

## **SPI Registers**

There are three internal registers which control the overall operation of the SPI interface. These are the SIMD data register and two registers SIMC0 and SIMC2. Note that the SIMC1 register is only used by the I<sup>2</sup>C interface.

| Register | Bit  |      |        |      |         |         |       |        |  |
|----------|------|------|--------|------|---------|---------|-------|--------|--|
| Name     | 7    | 6    | 5      | 4    | 3       | 2       | 1     | 0      |  |
| SIMC0    | SIM2 | SIM1 | SIM0   | _    | SIMDEB1 | SIMDEB0 | SIMEN | SIMICF |  |
| SIMD     | D7   | D6   | D5     | D4   | D3      | D2      | D1    | D0     |  |
| SIMC2    | D7   | D6   | CKPOLB | CKEG | MLS     | CSEN    | WCOL  | TRF    |  |

**SIM Registers List** 

## SPI Data Register - SIMD

The SIMD register is used to store the data being transmitted and received. The same register is used by both the SPI and I<sup>2</sup>C functions. Before the device writes data to the SPI bus, the actual data to be transmitted must be placed in the SIMD register. After the data is received from the SPI bus, the device can read it from the SIMD register. Any transmission or reception of data from the SPI bus must be made via the SIMD register.

# SIMD Register

#### SPI Control Registers - SIMC0/SIMC2

There are also two control registers for the SPI interface, SIMC0 and SIMC2. Note that the SIMC2 register also has the name SIMA which is used by the I<sup>2</sup>C function. The SIMC1 register is not used by the SPI function, only by the I<sup>2</sup>C function. Register SIMC0 is used to control the enable/disable function and to set the data transmission clock frequency. Although not connected with the SPI function, the SIMC0 register is also used to control the Peripheral Clock Prescaler. Register SIMC2 is used for other control functions such as LSB/MSB selection, write collision flag etc.

#### SIMC0 Register

| Bit  | 7    | 6    | 5    | 4 | 3       | 2       | 1     | 0      |
|------|------|------|------|---|---------|---------|-------|--------|
| Name | SIM2 | SIM1 | SIM0 | _ | SIMDEB1 | SIMDEB0 | SIMEN | SIMICF |
| R/W  | R/W  | R/W  | R/W  | _ | R/W     | R/W     | R/W   | R/W    |
| POR  | 1    | 1    | 1    | _ | 0       | 0       | 0     | 0      |

Bit 7~5 SIM2~SIM0: SIM Operating Mode Control

000: SPI master mode; SPI clock is  $f_{SYS}/4$  001: SPI master mode; SPI clock is  $f_{SYS}/16$  010: SPI master mode; SPI clock is  $f_{SYS}/64$  011: SPI master mode; SPI clock is  $f_{SUB}$ 

100: SPI master mode; SPI clock is STM CCRP match frequency/2

101: SPI slave mode 110: I<sup>2</sup>C slave mode 111: Unused mode

These bits setup the overall operating mode of the SIM function. As well as selecting if the I $^2$ C or SPI function, they are used to control the SPI Master/Slave selection and the SPI Master clock frequency. The SPI clock is a function of the system clock but can also be chosen to be sourced from  $f_{SUB}$  or the STM. If the SPI Slave Mode is selected then the clock will be supplied by an external Master device.

Bit 4 Unimplemented, read as "0"

Bit 3~2 **SIMDEB**[1:0]: I<sup>2</sup>C Debounce Time Selection

The SIMDEB[1:0] bits are of no used in SPI mode of SIM, please ignore these selection bits when operate in SPI mode.

Bit 1 SIMEN: SIM Control

0: Disable 1: Enable

The bit is the overall on/off control for the SIM interface. When the SIMEN bit is cleared to zero to disable the SIM interface, the SDI, SDO, SCK and \$\overline{SCS}\$, or SDA and SCL lines will be in a floating condition and the SIM operating current will be reduced to a minimum value. When the bit is high the SIM interface is enabled. The SIM configuration option must have first enabled the SIM interface for this bit to be effective. If the SIM is configured to operate as an SPI interface via the SIM2~SIM0 bits, the contents of the SPI control registers will remain at the previous settings when the SIMEN bit changes from low to high and should therefore be first initialised by the application program. If the SIM is configured to operate as an I²C interface via the SIM2~SIM0 bits and the SIMEN bit changes from low to high, the contents of the I²C control bits such as HTX and TXAK will remain at the previous settings and should therefore be first initialised by the application program while the relevant I²C flags such as HCF, HAAS, HBB, SRW and RXAK will be set to their default states.

Bit 0 **SIMICF**: SIM Incomplete Flag

0: SIM incompleted is not occurred

1: SIM incompleted is occurred

The SIMICF bit is determined by  $\overline{SCS}$  pin. When  $\overline{SCS}$  pin is set high, it will clear the SPI counter. Meanwhile, the interrupt is occurred and the incomplete flag, SIMICF, is set high.

Rev. 1.50 138 October 26, 2023

## SIMC2 Register

| Bit  | 7   | 6   | 5      | 4    | 3   | 2    | 1    | 0   |
|------|-----|-----|--------|------|-----|------|------|-----|
| Name | D7  | D6  | CKPOLB | CKEG | MLS | CSEN | WCOL | TRF |
| R/W  | R/W | R/W | R/W    | R/W  | R/W | R/W  | R/W  | R/W |
| POR  | 0   | 0   | 0      | 0    | 0   | 0    | 0    | 0   |

Bit 7~6 **D7~D6**: Undefined bit

This bit can be read or written by user software program.

Bit 5 CKPOLB: Determines the base condition of the clock line

0: The SCK line will be high when the clock is inactive

1: The SCK line will be low when the clock is inactive

The CKPOLB bit determines the base condition of the clock line, if the bit is high, then the SCK line will be low when the clock is inactive. When the CKPOLB bit is low, then the SCK line will be high when the clock is inactive.

Bit 4 CKEG: Determines SPI SCK active clock edge type

CKPOLB=0

0: SCK is high base level and data capture at SCK rising edge

1: SCK is high base level and data capture at SCK falling edge

CKPOLB=1

0: SCK is low base level and data capture at SCK falling edge

1: SCK is low base level and data capture at SCK rising edge

The CKEG and CKPOLB bits are used to setup the way that the clock signal outputs and inputs data on the SPI bus. These two bits must be configured before data transfer is executed otherwise an erroneous clock edge may be generated. The CKPOLB bit determines the base condition of the clock line, if the bit is high, then the SCK line will be low when the clock is inactive. When the CKPOLB bit is low, then the SCK line will be high when the clock is inactive. The CKEG bit determines active clock edge type which depends upon the condition of CKPOLB bit.

Bit 3 MLS: SPI Data shift order

0: LSB

1: MSB

This is the data shift select bit and is used to select how the data is transferred, either MSB or LSB first. Setting the bit high will select MSB first and low for LSB first.

Bit 2 CSEN: SPI SCS pin Control

0: Disable

1: Enable

The CSEN bit is used as an enable/disable for the  $\overline{SCS}$  pin. If this bit is low, then the  $\overline{SCS}$  pin will be disabled and placed into a floating condition. If the bit is high the  $\overline{SCS}$  pin will be enabled and used as a select pin.

Bit 1 WCOL: SPI Write Collision flag

0: No collision

1: Collision

The WCOL flag is used to detect if a data collision has occurred. If this bit is high it means that data has been attempted to be written to the SIMD register during a data transfer operation. This writing operation will be ignored if data is being transferred. The bit can be cleared by the application program.

Bit 0 TRF: SPI Transmit/Receive Complete flag

0: Data is being transferred

1: SPI data transmission is completed

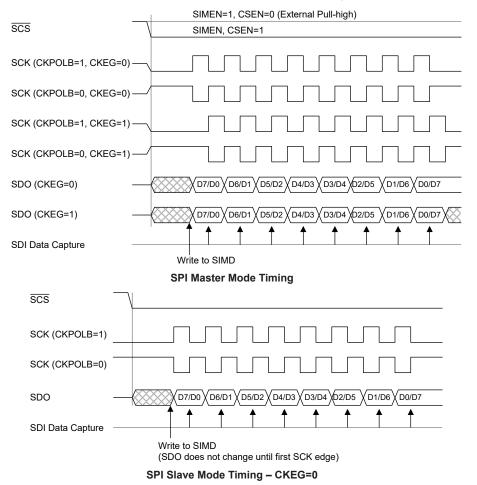

The TRF bit is the Transmit/Receive Complete flag and is set high automatically when an SPI data transmission is completed, but must cleared to zero by the application program. It can be used to generate an interrupt.

#### **SPI Communication**

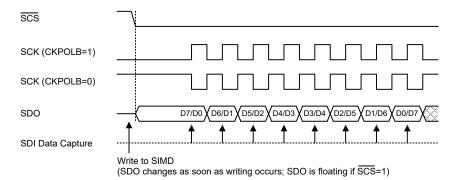

After the SPI interface is enabled by setting the SIMEN bit high, then in the Master Mode, when data is written to the SIMD register, transmission/reception will begin simultaneously. When the data transfer is complete, the TRF flag will be set automatically, but must be cleared using the application program. In the Slave Mode, when the clock signal from the master has been received, any data in the SIMD register will be transmitted and any data on the SDI pin will be shifted into the SIMD register. The master should output an SCS signal to enable the slave device before a clock signal is provided. The slave data to be transferred should be well prepared at the appropriate moment relative to the SCK signal depending upon the configurations of the CKPOLB bit and CKEG bit. The accompanying timing diagram shows the relationship between the slave data and SCK signal for various configurations of the CKPOLB and CKEG bits.

The SPI Master mode will continue to function if the SPI clock is running.

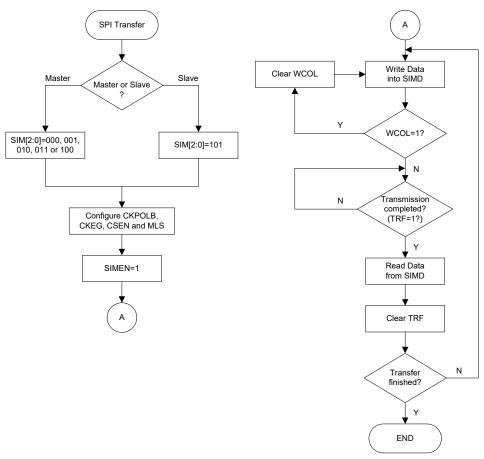

Rev. 1.50 140 October 26, 2023

Note: For SPI slave mode, if SIMEN=1 and CSEN=0, SPI is always enabled and ignores the  $\overline{SCS}$  level.

# SPI Slave Mode Timing - CKEG=1

**SPI Transfer Control Flowchart** 

Rev. 1.50 October 26, 2023

#### SPI Bus Enable/Disable

To enable the SPI bus, set CSEN=1 and SCS=0, then wait for data to be written into the SIMD (TXRX buffer) register. For the Master Mode, after data has been written to the SIMD (TXRX buffer) register, then transmission or reception will start automatically. When all the data has been transferred, the TRF bit should be set. For the Slave Mode, when clock pulses are received on SCK, data in the TXRX buffer will be shifted out or data on SDI will be shifted in.

When the SPI bus is disabled, the SCK, SDI, SDO and  $\overline{SCS}$  can become I/O pins or other pin-shared functions using the corresponding pin-shared control bits.

#### **SPI Operation Steps**

All communication is carried out using the 4-line interface for either Master or Slave Mode.

The CSEN bit in the SIMC2 register controls the overall function of the SPI interface. Setting this bit high will enable the SPI interface by allowing the  $\overline{SCS}$  line to be active, which can then be used to control the SPI interface. If the CSEN bit is low, the SPI interface will be disabled and the  $\overline{SCS}$  line will be in a floating condition and can therefore not be used for control of the SPI interface. If the CSEN bit and the SIMEN bit in the SIMC0 are set high, this will place the SDI line in a floating condition and the SDO line high. If in Master Mode the SCK line will be either high or low depending upon the clock polarity selection bit CKPOLB in the SIMC2 register. If in Slave Mode the SCK line will be in a floating condition. If the SIMEN bit is low, then the bus will be disabled and the  $\overline{SCS}$ , SDI, SDO and SCK will all become I/O pins or the other functions using the corresponding pin-shared control bits. In the Master Mode the Master will always generate the clock signal. The clock and data transmission will be initiated after data has been written into the SIMD register. In the Slave Mode, the clock signal will be received from an external master device for both data transmission and reception. The following sequences show the order to be followed for data transfer in both Master and Slave Mode.

## **Master Mode**

- Step 1
  - Select the SPI Master mode and clock source using the SIM2~SIM0 bits in the SIMC0 control register.
- Step 2

Setup the CSEN bit and setup the MLS bit to choose if the data is MSB or LSB first, this setting must be the same with the Slave devices.

- Step 3
  - Setup the SIMEN bit in the SIMC0 control register to enable the SPI interface.
- Step 4

For write operations: write the data to the SIMD register, which will actually place the data into the TXRX buffer. Then use the SCK and SDO lines to output the data. After this, go to step 5.

For read operations: the data transferred in on the SDI line will be stored in the TXRX buffer until all the data has been received at which point it will be latched into the SIMD register.

- Step 5
  - Check the WCOL bit if set high then a collision error has occurred so return to step 4. If equal to zero then go to the following step.
- Step 6

Check the TRF bit or wait for an SIM SPI serial bus interrupt.

Rev. 1.50 142 October 26, 2023

• Step 7

Read data from the SIMD register.

• Step 8

Clear TRF.

• Step 9

Go to step 4.

#### Slave Mode

• Step 1

Select the SPI Slave mode using the SIM2~SIM0 bits in the SIMC0 control register.

• Step 2

Setup the CSEN bit and setup the MLS bit to choose if the data is MSB or LSB first, this setting must be the same with the Master devices.

Step 3

Setup the SIMEN bit in the SIMC0 control register to enable the SPI interface.

all the data has been received at which point it will be latched into the SIMD register.

Step 4

For write operations: write the data to the SIMD register, which will actually place the data into the TXRX buffer. Then wait for the master clock SCK and  $\overline{SCS}$  signal. After this, go to step 5. For read operations: the data transferred in on the SDI line will be stored in the TXRX buffer until

Sten 5

Check the WCOL bit if set high then a collision error has occurred so return to step 4. If equal to zero then go to the following step.

• Step 6

Check the TRF bit or wait for an SIM SPI serial bus interrupt.

• Step 7

Read data from the SIMD register.

• Step 8

Clear TRF.

· Step 9

Go to step 4.

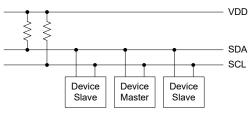

#### **Error Detection**

The WCOL bit in the SIMC2 register is provided to indicate errors during data transfer. The bit is set by the SPI serial Interface but must be cleared by the application program. This bit indicates that a data collision has occurred which happens if a write to the SIMD register takes place during a data transfer operation and will prevent the write operation from continuing.

#### I<sup>2</sup>C Interface

The I<sup>2</sup>C interface is used to communicate with external peripheral devices such as sensors etc. Originally developed by Philips, it is a two line low speed serial interface for synchronous serial data transfer. The advantage of only two lines for communication, relatively simple communication protocol and the ability to accommodate multiple devices on the same bus has made it an extremely popular interface type for many applications.

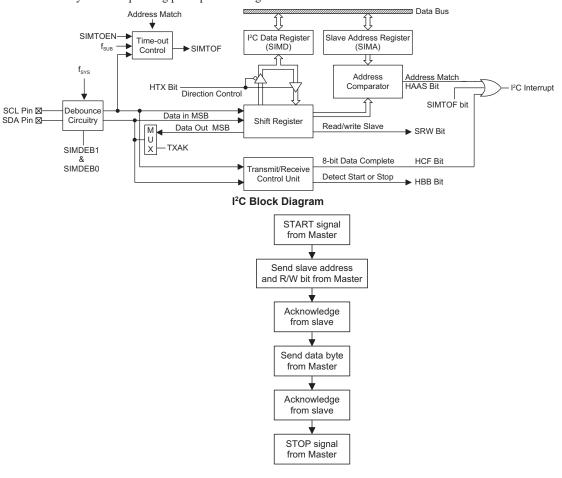

I<sup>2</sup>C Master/Slave Bus Connection

## I<sup>2</sup>C Interface Operation

The I<sup>2</sup>C serial interface is a two line interface, a serial data line, SDA, and serial clock line, SCL. As many devices may be connected together on the same bus, their outputs are both open drain types. For this reason it is necessary that external pull-high resistors are connected to these outputs. Note that no chip select line exists, as each device on the I<sup>2</sup>C bus is identified by a unique address which will be transmitted and received on the I<sup>2</sup>C bus.

When two devices communicate with each other on the bidirectional I<sup>2</sup>C bus, one is known as the master device and one as the slave device. Both master and slave can transmit and receive data; however, it is the master device that has overall control of the bus. For the device, which only operate in slave mode, there are two methods of transferring data on the I<sup>2</sup>C bus, the slave transmit mode and the slave receive mode. The pull-up control function pin-shared with SCL/SDA pin is still applicable even if I<sup>2</sup>C device is activated and the related internal pull-up register could be controlled by its corresponding pull-up control register.

Rev. 1.50 144 October 26, 2023

The SIMDEB1 and SIMDEB0 bits determine the debounce time of the I<sup>2</sup>C interface. This uses the system clock to in effect add a debounce time to the external clock to reduce the possibility of glitches on the clock line causing erroneous operation. The debounce time, if selected, can be chosen to be either 2 or 4 system clocks. To achieve the required I<sup>2</sup>C data transfer speed, there exists a relationship between the system clock, f<sub>SYS</sub>, and the I<sup>2</sup>C debounce time. For either the I<sup>2</sup>C Standard or Fast mode operation, users must take care of the selected system clock frequency and the configured debounce time to match the criterion shown in the following table.

| I <sup>2</sup> C Debounce Time Selection | I <sup>2</sup> C Standard Mode (100kHz) | I <sup>2</sup> C Fast Mode (400kHz) |  |  |
|--|---|-------------------------------------|--|--|
| No Debounce                              | f <sub>SYS</sub> > 2MHz                 | f <sub>SYS</sub> > 4MHz             |  |  |
| 2 system clock debounce                  | f <sub>SYS</sub> > 4MHz                 | f <sub>SYS</sub> > 8MHz             |  |  |
| 4 system clock debounce                  | f <sub>SYS</sub> > 4MHz                 | f <sub>SYS</sub> > 8MHz             |  |  |

I<sup>2</sup>C Minimum f<sub>SYS</sub> Frequency Requirement

### I<sup>2</sup>C Registers

There are three control registers associated with the I<sup>2</sup>C bus, SIMC0, SIMC1 and SIMTOC, one address register, SIMA and one data register, SIMD.

| Register |         |        |         | В       |         |         |         |         |
|----------|---------|--------|---------|---------|---------|---------|---------|---------|
| Name     | 7       | 6      | 5       | 4       | 3       | 2       | 1       | 0       |
| SIMC0    | SIM2    | SIM1   | SIM0    | _       | SIMDEB1 | SIMDEB0 | SIMEN   | SIMICF  |
| SIMC1    | HCF     | HAAS   | HBB     | HTX     | TXAK    | SRW     | IAMWU   | RXAK    |
| SIMD     | D7      | D6     | D5      | D4      | D3      | D2      | D1      | D0      |
| SIMA     | A6      | A5     | A4      | A3      | A2      | A1      | A0      | D0      |
| SIMTOC   | SIMTOEN | SIMTOF | SIMTOS5 | SIMTOS4 | SIMTOS3 | SIMTOS2 | SIMTOS1 | SIMTOS0 |

I<sup>2</sup>C Register List

#### I<sup>2</sup>C Control Registers - SIMC0, SIMC1, SIMTOC

There are three control registers for the I2C interface, SIMC0, SIMC1 and SIMTOC. The register SIMC0 is used to control the enable/disable function and to select the I2C slave mode and debounce time. The SIMC1 register contains the relevant flags which are used to indicate the I2C communication status. Another register, SIMTOC, is used to control the I2C time-out function and is described in the corresponding section.

#### SIMC0 Register

| Bit  | 7    | 6    | 5    | 4 | 3       | 2       | 1     | 0      |
|------|------|------|------|---|---------|---------|-------|--------|
| Name | SIM2 | SIM1 | SIM0 | _ | SIMDEB1 | SIMDEB0 | SIMEN | SIMICF |
| R/W  | R/W  | R/W  | R/W  | _ | R/W     | R/W     | R/W   | R/W    |
| POR  | 1    | 1    | 1    | _ | 0       | 0       | 0     | 0      |

Bit 7~5 SIM2~SIM0: SIM Operating Mode Control

000: SPI master mode; SPI clock is  $f_{\text{SYS}}/4$ 

001: SPI master mode; SPI clock is f<sub>SYS</sub>/16 010: SPI master mode; SPI clock is f<sub>SYS</sub>/64

011: SPI master mode; SPI clock is f<sub>SUB</sub>

100: SPI master mode; SPI clock is STM CCRP match frequency/2

101: SPI slave mode 110: I<sup>2</sup>C slave mode

111: Unused mode

These bits setup the overall operating mode of the SIM function. As well as selecting if the I $^2$ C or SPI function, they are used to control the SPI Master/Slave selection and the SPI Master clock frequency. The SPI clock is a function of the system clock but can also be chosen to be sourced from  $f_{SUB}$  or the STM. If the SPI Slave Mode is selected then the clock will be supplied by an external Master device.

Bit 4 Unimplemented, read as "0"

Bit 3~2 **SIMDEB1~SIMDEB0**: I<sup>2</sup>C Debounce Time Selection

00: No debounce

01: 2 system clock debounce 1x: 4 system clock debounce

Bit 1 SIMEN: SIM Control

0: Disable 1: Enable

The bit is the overall on/off control for the SIM interface. When the SIMEN bit is cleared to zero to disable the SIM interface, the SDI, SDO, SCK and  $\overline{\text{SCS}}$ , or SDA and SCL lines will be in a floating condition and the SIM operating current will be reduced to a minimum value. When the bit is high the SIM interface is enabled. The SIM configuration option must have first enabled the SIM interface for this bit to be effective. If the SIM is configured to operate as an SPI interface via the SIM2~SIM0 bits, the contents of the SPI control registers will remain at the previous settings when the SIMEN bit changes from low to high and should therefore be first initialised by the application program. If the SIM is configured to operate as an I²C interface via the SIM2~SIM0 bits and the SIMEN bit changes from low to high, the contents of the I²C control bits such as HTX and TXAK will remain at the previous settings and should therefore be first initialised by the application program while the relevant I²C flags such as HCF, HAAS, HBB, SRW and RXAK will be set to their default states.

Bit 0 **SIMICF**: SIM Incomplete Flag

SIMICF is of no used in I<sup>2</sup>C mode of SIM, please ignore this flag when operate in I<sup>2</sup>C mode.

#### SIMC1 Register

| Bit  | 7   | 6    | 5   | 4   | 3    | 2   | 1     | 0    |
|------|-----|------|-----|-----|------|-----|-------|------|
| Name | HCF | HAAS | HBB | HTX | TXAK | SRW | IAMWU | RXAK |
| R/W  | R   | R    | R   | R/W | R/W  | R   | R/W   | R    |
| POR  | 1   | 0    | 0   | 0   | 0    | 0   | 0     | 1    |

Bit 7 HCF: I<sup>2</sup>C Bus data transfer completion flag

0: Data is being transferred

1: Completion of an 8-bit data transfer

The HCF flag is the data transfer flag. This flag will be zero when data is being transferred. Upon completion of an 8-bit data transfer the flag will go high and an interrupt will be generated.

Bit 6 HAAS: I<sup>2</sup>C Bus address match flag

0: Not address match

1: Address match

The HAAS flag is the address match flag. This flag is used to determine if the slave device address is the same as the master transmit address. If the addresses match then this bit will be high, if there is no match then the flag will be low.

Bit 5 **HBB**: I<sup>2</sup>C Bus busy flag

0: I2C Bus is not busy

1: I<sup>2</sup>C Bus is busy

The HBB flag is the I<sup>2</sup>C busy flag. This flag will be "1" when the I<sup>2</sup>C bus is busy which will occur when a START signal is detected. The flag will be cleared to zero when the bus is free which will occur when a STOP signal is detected.

Bit 4 HTX: Select I<sup>2</sup>C slave device is transmitter or receiver

0: Slave device is the receiver

1: Slave device is the transmitter

Bit 3 TXAK: I<sup>2</sup>C Bus transmit acknowledge flag

0: Slave send acknowledge flag

1: Slave do not send acknowledge flag

The TXAK bit is the transmit acknowledge flag. After the slave device receipt of 8-bit of data, this bit will be transmitted to the bus on the 9th clock from the slave device. The slave device must always set TXAK bit to "0" before further data is received.

Bit 2 SRW: I<sup>2</sup>C Slave Read/Write flag

0: Slave device should be in receive mode

1: Slave device should be in transmit mode

The SRW flag is the I<sup>2</sup>C Slave Read/Write flag. This flag determines whether the master device wishes to transmit or receive data from the I<sup>2</sup>C bus. When the transmitted address and slave address is match, that is when the HAAS flag is set high, the slave device will check the SRW flag to determine whether it should be in transmit mode or receive mode. If the SRW flag is high, the master is requesting to read data from the bus, so the slave device should be in transmit mode. When the SRW flag is zero, the master will write data to the bus, therefore the slave device should be in receive mode to read this data.

Bit 1 IAMWU: I<sup>2</sup>C Address Match Wake Up function Control

0: Disable 1: Enable.

This bit should be set to 1 to enable the I<sup>2</sup>C address match wake up from the SLEEP or IDLE Mode. If the IAMWU bit has been set before entering either the SLEEP or IDLE mode to enable the I<sup>2</sup>C address match wake up, then this bit must be cleared by the application program after wake-up to ensure correct device operation.

Bit 0 RXAK: I<sup>2</sup>C Bus Receive acknowledge flag

0: Slave receives acknowledge flag

1: Slave does not receive acknowledge flag

The RXAK flag is the receiver acknowledge flag. When the RXAK flag is "0", it means that a acknowledge signal has been received at the 9th clock, after 8 bits of data have been transmitted. When the slave device in the transmit mode, the slave device checks the RXAK flag to determine if the master receive wishes to receive the next byte. The slave transmitter will therefore continue sending out data until the RXAK flag is "1". When this occurs, the slave transmitter will release the SDA line to allow the master to send a STOP signal to release the I<sup>2</sup>C bus.

#### I<sup>2</sup>C Data Register – SIMD

The SIMD register is used to store the data being transmitted and received. The same register is used by both the SPI and I<sup>2</sup>C functions. Before the device writes data to the I<sup>2</sup>C bus, the actual data to be transmitted must be placed in the SIMD register. After the data is received from the I<sup>2</sup>C bus, the device can read it from the SIMD register. Any transmission or reception of data from the I<sup>2</sup>C bus must be made via the SIMD register.

### SIMD Register

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | D7  | D6  | D5  | D4  | D3  | D2  | D1  | D0  |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | Х   | Х   | Х   | Х   | Х   | Х   | Х   | Х   |

"x" unknown

Bit  $7 \sim 0$  **D7~D0**: SIM data register bit  $7 \sim$  bit 0

#### I<sup>2</sup>C Address Register - SIMA

The SIMA register is also used by the SPI interface but has the name SIMC2. The SIMA register is the location where the 7-bit slave address of the slave device is stored. Bits  $7\sim1$  of the SIMA register define the device slave address. Bit 0 is not implemented.

When a master device, which is connected to the I<sup>2</sup>C bus, sends out an address, which matches the slave address in the SIMA register, the slave device will be selected. Note that the SIMA register locates at the same register address as SIMC2 which is used by the SPI interface.

### SIMA Register

| Bit  | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|
| Name | A6  | A5  | A4  | A3  | A2  | A1  | A0  | D0  |
| R/W  | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| POR  | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

Bit  $7 \sim 1$  **A6~A0**:  $I^2C$  slave address

A6~ A0 is the I2C slave address bit  $6 \sim$  bit 0.

Bit 0 **D0: Reserved bit** 

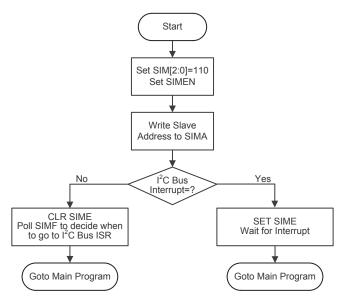

This bit can be read or written by user software program.

#### I<sup>2</sup>C Bus Communication

Communication on the I<sup>2</sup>C bus requires four separate steps, a START signal, a slave device address transmission, a data transmission and finally a STOP signal. When a START signal is placed on the I<sup>2</sup>C bus, all devices on the bus will receive this signal and be notified of the imminent arrival of data on the bus. The first seven bits of the data will be the slave address with the first bit being the MSB. If the address of the slave device matches that of the transmitted address, the HAAS bit in the SIMC1 register will be set and an I<sup>2</sup>C interrupt will be generated. After entering the interrupt service routine, the slave device must first check the condition of the HAAS bit and SIMTOF bit to determine whether the interrupt source originates from an address match or from the completion of an 8-bit data transfer or from the I<sup>2</sup>C communication time-out. During a data transfer, note that after the 7-bit slave address has been transmitted, the following bit, which is the 8th bit, is the read/write bit whose value will be placed in the SRW bit. This bit will be checked by the slave device to determine whether to go into transmit or receive mode. Before any transfer of data to or from the I<sup>2</sup>C bus, the microcontroller must initialise the bus, the following are steps to achieve this:

- Step 1
   Set the SIM2~SIM0 bits to "110" and the SIMEN bits to "1" in the SIMC0 register to enable the I<sup>2</sup>C bus.
- Step 2
   Write the slave address to the I<sup>2</sup>C bus address register SIMA.
- Step 3
   Set the SIME interrupt enable bit o enable the SIM interrupt.

I<sup>2</sup>C Bus Initialisation Flow Chart

### I2C Bus Start Signal

The START signal can only be generated by the master device connected to the I<sup>2</sup>C bus and not by the slave device. This START signal will be detected by all devices connected to the I<sup>2</sup>C bus. When detected, this indicates that the I<sup>2</sup>C bus is busy and therefore the HBB bit will be set. A START condition occurs when a high to low transition on the SDA line takes place when the SCL line remains high.

#### **Slave Address**

The transmission of a START signal by the master will be detected by all devices on the I<sup>2</sup>C bus. To determine which slave device the master wishes to communicate with, the address of the slave device will be sent out immediately following the START signal. All slave devices, after receiving this 7-bit address data, will compare it with their own 7-bit slave address. If the address sent out by the master matches the internal address of the microcontroller slave device, then an internal I<sup>2</sup>C bus interrupt signal will be generated. The next bit following the address, which is the 8th bit, defines the read/write status and will be saved to the SRW bit of the SIMC1 register. The slave device will then transmit an acknowledge bit, which is a low level, as the 9th bit. The slave device will also set the status flag HAAS when the addresses match.

As an I<sup>2</sup>C bus interrupt can come from three sources, when the program enters the interrupt subroutine, the HAAS bit and SIMTOF bit should be examined to see whether the interrupt source has come from a matching slave address or from the completion of a data byte transfer or from the I<sup>2</sup>C communication time-out. When a slave address is matched, the device must be placed in either the transmit mode and then write data to the SIMD register, or in the receive mode where it must implement a dummy read from the SIMD register to release the SCL line.

### I<sup>2</sup>C Bus Read/Write Signal

The SRW bit in the SIMC1 register defines whether the slave device wishes to read data from the I<sup>2</sup>C bus or write data to the I<sup>2</sup>C bus. The slave device should examine this bit to determine if it is to be a transmitter or a receiver. If the SRW flag is "1" then this indicates that the master device wishes to read data from the I<sup>2</sup>C bus, therefore the slave device must be setup to send data to the I<sup>2</sup>C bus as a transmitter. If the SRW flag is "0" then this indicates that the master wishes to send data to the I<sup>2</sup>C bus, therefore the slave device must be setup to read data from the I<sup>2</sup>C bus as a receiver.

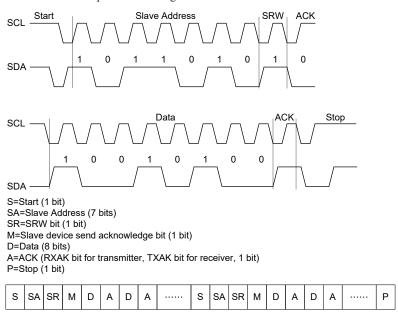

### I<sup>2</sup>C Bus Slave Address Acknowledge Signal

After the master has transmitted a calling address, any slave device on the I<sup>2</sup>C bus, whose own internal address matches the calling address, must generate an acknowledge signal. The acknowledge signal will inform the master that a slave device has accepted its calling address. If no acknowledge signal is received by the master then a STOP signal must be transmitted by the master to end the communication. When the HAAS flag is high, the addresses have matched and the slave device must check the SRW flag to determine if it is to be a transmitter or a receiver. If the SRW flag is high, the slave device should be setup to be a transmitter so the HTX bit in the SIMC1 register should be set high. If the SRW flag is low, then the microcontroller slave device should be setup as a receiver and the HTX bit in the SIMC1 register should be cleared to zero.

### I<sup>2</sup>C Bus Data and Acknowledge Signal

The transmitted data is 8-bit wide and is transmitted after the slave device has acknowledged receipt of its slave address. The order of serial bit transmission is the MSB first and the LSB last. After receipt of 8-bit of data, the receiver must transmit an acknowledge signal, level "0", before it can receive the next data byte. If the slave transmitter does not receive an acknowledge bit signal from the master receiver, then the slave transmitter will release the SDA line to allow the master to send a STOP signal to release the I<sup>2</sup>C Bus. The corresponding data will be stored in the SIMD register. If setup as a transmitter, the slave device must first write the data to be transmitted into the SIMD register. If setup as a receiver, the slave device must read the transmitted data from the SIMD register.

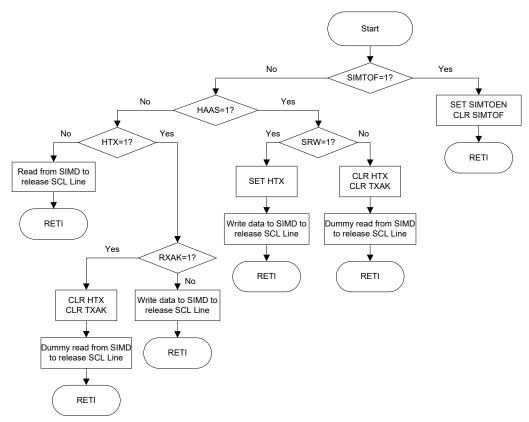

When the slave receiver receives the data byte, it must generate an acknowledge bit, known as TXAK, on the 9th clock. The slave device, which is setup as a transmitter will check the RXAK bit in the SIMC1 register to determine if it is to send another data byte, if not then it will release the SDA line and await the receipt of a STOP signal from the master.

I<sup>2</sup>C Communication Timing Diagram

Note: \*When a slave address is matched, the device must be placed in either the transmit mode and then write data to the SIMD register, or in the receive mode where it must implement a dummy read from the SIMD register to release the SCL line.

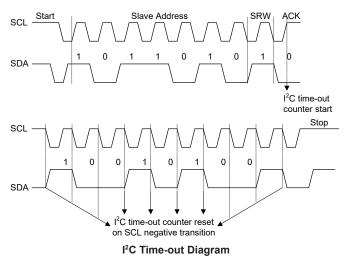

I<sup>2</sup>C Bus ISR Flow Chart

## I<sup>2</sup>C Time-out Control

In order to reduce the I2C lockup problem due to reception of erroneous clock sources, a time-out function is provided. If the clock source connected to the I2C bus is not received for a while, then the I2C circuitry and registers will be reset after a certain time-out period. The time-out counter starts to count on an I2C bus "START" & "address match" condition, and is cleared by an SCL falling edge. Before the next SCL falling edge arrives, if the time elapsed is greater than the time-out period specified by the SIMTOC register, then a time-out condition will occur. The time-out function will stop when an I2C "STOP" condition occurs.

When an I<sup>2</sup>C time-out counter overflow occurs, the counter will stop and the SIMTOEN bit will be cleared to zero and the SIMTOF bit will be set high to indicate that a time-out condition has occurred. The time-out condition will also generate an interrupt which uses the SIM interrupt vector. When an I<sup>2</sup>C time-out occurs, the I<sup>2</sup>C internal circuitry will be reset and the registers will be reset into the following condition:

| Register          | After I <sup>2</sup> C Time-out |
|-------------------|---------------------------------|
| SIMD, SIMA, SIMC0 | No change                       |
| SIMC1             | Reset to POR condition          |

I<sup>2</sup>C Registers after Time-out

The SIMTOF flag can be cleared by the application program. There are 64 time-out period selections which can be selected using the SIMTOS5~SIMTOS0 bits in the SIMTOC register. The time-out duration is calculated by the formula:  $((1\sim64)\times(32/f_{SUB}))$ . This gives a time-out period which ranges from about 1ms to 64ms.

### SIMTOC Register

| Bit  | 7       | 6      | 5       | 4       | 3       | 2       | 1       | 0       |
|------|---------|--------|---------|---------|---------|---------|---------|---------|
| Name | SIMTOEN | SIMTOF | SIMTOS5 | SIMTOS4 | SIMTOS3 | SIMTOS2 | SIMTOS1 | SIMTOS0 |
| R/W  | R/W     | R/W    | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     |
| POR  | 0       | 0      | 0       | 0       | 0       | 0       | 0       | 0       |

Bit 7 **SIMTOEN**: SIM I<sup>2</sup>C Time-out control

0: Disable 1: Enable

Bit 6 **SIMTOF**: SIM I<sup>2</sup>C Time-out flag

0: No time-out occurred1: Time-out occurred

Bit 5~0 **SIMTOS5~SIMTOS0**: SIM I<sup>2</sup>C Time-out period selection

I<sup>2</sup>C Time-out clock source is f<sub>SUB</sub>/32.

 $I^2C$  Time-out period is equal to (SIMTOS[5:0]+1)×(32/ $f_{SUB}$ ).

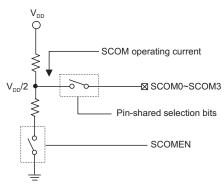

## **LCD SCOM Function**

The devices have the capability of driving external LCD panels. The common pins for LCD driving, SCOM0~SCOM3, are pin shared with certain pin on the I/O ports. The LCD signals(COM and SEG) are generated using the application program.

### **LCD Operation**

An external LCD panel can be driven using this device by configuring the I/O pins as common pins and segment pins. The LCD driver function is controlled using the SCOMC register which in addition to controlling the overall on/off function also controls the bias voltage setup function. This enables the LCD COM driver to generate the necessary  $V_{DD}/2$  voltage levels for LCD 1/2 bias operation.

**LCD COM Bias** 

The SCOMEN bit in the SCOMC register is the overall master control for the LCD driver. The LCD SCOMn pin is selected to be used for LCD driving by the corresponding pin-shared function selection bits. Note that the Port Control register does not need to first setup the pins as outputs to enable the LCD driver operation.

### **LCD Bias Current Control**

The LCD COM driver enables a range of selections to be provided to suit the requirement of the LCD panel which are being used. The bias resistor choice is implemented using the ISEL1 and ISEL0 bits in the SCOMC register.

### SCOMC Register

| Bit  | 7 | 6     | 5     | 4      | 3 | 2 | 1 | 0 |
|------|---|-------|-------|--------|---|---|---|---|
| Name | _ | ISEL1 | ISEL0 | SCOMEN | _ | _ | _ | _ |
| R/W  | _ | R/W   | R/W   | R/W    | _ | _ | _ | _ |
| POR  | _ | 0     | 0     | 0      | _ | _ | _ | _ |

Bit 7 Unimplemented, read as "0"

Bit  $6\sim5$  **ISEL1~ISEL0**: Select R type LCD bias current ( $V_{DD}=5V$ )

00:  $2\times100$ kΩ (1/2 Bias),  $I_{BIAS}$ =25μA 01:  $2\times50$ kΩ (1/2 Bias),  $I_{BIAS}$ =50μA 10:  $2\times25$ kΩ (1/2 Bias),  $I_{BIAS}$ =100μA 11:  $2\times12.5$ kΩ (1/2 Bias),  $I_{BIAS}$ =200μA

Bit 4 SCOMEN: LCD function enable control bit

0: Disable 1: Enable

When SCOMEN is set, it will turn on the DC path of resistor to generate  $1/2\ V_{DD}$  bias voltage.

Bit 3~0 Unimplemented, read as "0"

## **Low Voltage Detector – LVD**

The devices have a Low Voltage Detector function, also known as LVD. This enabled the device to monitor the power supply voltage,  $V_{DD}$ , and provide a warning signal should it fall below a certain level. This function may be especially useful in battery applications where the supply voltage will gradually reduce as the battery ages, as it allows an early warning battery low signal to be generated. The Low Voltage Detector also has the capability of generating an interrupt signal.

### **LVD Register**

The Low Voltage Detector function is controlled using a single register with the name LVDC. Three bits in this register, VLVD2~VLVD0, are used to select one of eight fixed voltages below which a low voltage condition will be determined. A low voltage condition is indicated when the LVDO bit is set. If the LVDO bit is low, this indicates that the V<sub>DD</sub> voltage is above the preset low voltage value. The LVDEN bit is used to control the overall on/off function of the low voltage detector. Setting the bit high will enable the low voltage detector. Clearing the bit to zero will switch off the internal low voltage detector circuits. As the low voltage detector will consume a certain amount of power, it may be desirable to switch off the circuit when not in use, an important consideration in power sensitive battery powered applications.

### LVDC Register

| Bit  | 7 | 6 | 5    | 4     | 3 | 2     | 1     | 0     |
|------|---|---|------|-------|---|-------|-------|-------|
| Name | _ | _ | LVDO | LVDEN | _ | VLVD2 | VLVD1 | VLVD0 |
| R/W  | _ | _ | R    | R/W   | _ | R/W   | R/W   | R/W   |
| POR  | _ | _ | 0    | 0     | _ | 0     | 0     | 0     |

Bit 7~6 Unimplemented, read as "0"

Bit 5 LVDO: LVD Output Flag

0: No Low Voltage Detected

1: Low Voltage Detected

Bit 4 LVDEN: Low Voltage Detector Control

0: Disable 1: Enable

Bit 3 Unimplemented, read as "0"

111: 4.0V

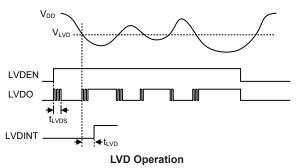

Bit 2~0 VLVD2~VLVD0: Select LVD Voltage

000: Undefined 001: Undefined 010: Undefined 011: 2.7V 100: 3.0V 101: 3.3V 110: 3.6V

### **LVD Operation**

The Low Voltage Detector function operates by comparing the power supply voltage,  $V_{DD}$ , with a pre-specified voltage level stored in the LVDC register. This has a range of between 2.7V and 4.0V. When the power supply voltage,  $V_{DD}$ , falls below this pre-determined value, the LVDO bit will be set high indicating a low power supply voltage condition. The Low Voltage Detector function is supplied by a reference voltage which will be automatically enabled. When the device is powered down the low voltage detector will remain active if the LVDEN bit is high. After enabling the Low Voltage Detector, a time delay  $t_{\rm LVDS}$  should be allowed for the circuitry to stabilise before reading the LVDO bit. Note also that as the  $V_{\rm DD}$  voltage may rise and fall rather slowly, at the voltage nears that of  $V_{\rm LVD}$ , there may be multiple bit LVDO transitions.

The Low Voltage Detector also has its own interrupt, providing an alternative means of low voltage detection, in addition to polling the LVDO bit. The interrupt will only be generated after a delay of  $t_{\text{LVD}}$  after the LVDO bit has been set high by a low voltage condition. In this case, the LVF interrupt request flag will be set, causing an interrupt to be generated if  $V_{\text{DD}}$  falls below the preset LVD voltage. This will cause the device to wake-up from the SLEEP or IDLE Mode, however if the Low Voltage Detector wake up function is not required then the LVF flag should be first set high before the device enters the SLEEP or IDLE Mode.

When LVD function is enabled, it is recommenced to clear LVD flag first, and then enables interrupt function to avoid mistake action.

## Interrupts

Interrupts are an important part of any microcontroller system. When an external event or an internal function such as a Timer Module or an A/D converter requires microcontroller attention, their corresponding interrupt will enforce a temporary suspension of the main program allowing the microcontroller to direct attention to their respective needs. The device contains several external interrupt and internal interrupt functions. The external interrupts are generated by the action of the external INT0~INT2 pins, while the internal interrupts are generated by various internal functions such as the Timer Modules(TMs), Time Bases, Serial Interface Module (SIM), Over Current Protections (OCP), Over Voltage Protections (OVP), Under Voltage Protections (UVP), Low Voltage Detector (LVD), EEPROM and the A/D converter.

## **Interrupt Registers**

Overall interrupt control, which basically means the setting of request flags when certain microcontroller conditions occur and the setting of interrupt enable bits by the application program, is controlled by a series of registers, located in the Special Purpose Data Memory. The registers fall into three categories. The first is the INTC0~INTC3 registers which setup the primary interrupts, the second is the MFI0~MFI1 registers which setup the Multi-function interrupts. Finally there is an INTEG register to setup the external interrupts trigger edge type.

Each register contains a number of enable bits to enable or disable individual registers as well as interrupt flags to indicate the presence of an interrupt request. The naming convention of these follows a specific pattern. First is listed an abbreviated interrupt type, then the (optional) number of that interrupt followed by either an "E" for enable/disable bit or "F" for request flag.

| Function                 | Enable Bit | Request Flag | Notes    |  |
|--------------------------|------------|--------------|----------|--|
| Global                   | EMI        | _            | _        |  |
| INTn Pin                 | INTnE      | INTnF        | n=0~2    |  |
| Over Current Protection  | OCPnE      | OCPnF        | n=0 or 1 |  |
| Under Voltage Protection | UVPnE      | UVPnF        | n=0 or 1 |  |

0: No request1: Interrupt request

Bit 4 **PTMPF**: PTM Comparator P match interrupt request flag

0: No request

1: Interrupt request

Bit 3 Unimplemented, read as "0"

Bit 2 ADE: A/D Converter interrupt control

0: Disable 1: Enable

Bit 1 **PTMAE**: PTM Comparator A match interrupt control

0: Disable 1: Enable

Bit 0 **PTMPE**: PTM Comparator P match interrupt control

0: Disable 1: Enable

### **Interrupt Operation**

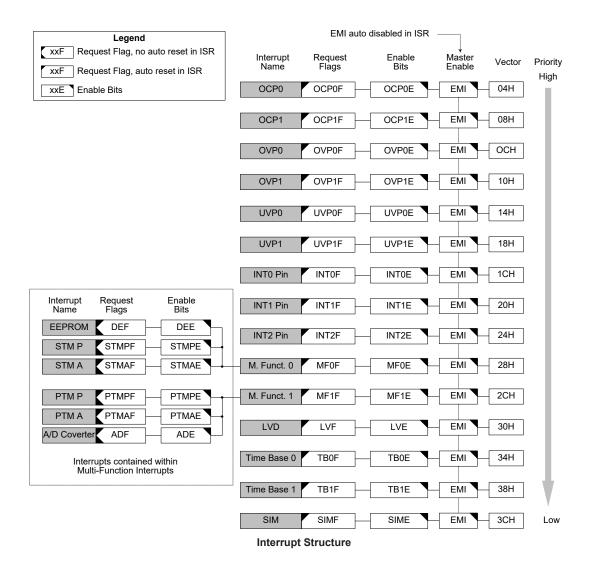

When the conditions for an interrupt event occur, such as a TM Comparator P, Comparator A match or A/D conversion completion etc., the relevant interrupt request flag will be set. Whether the request flag actually generates a program jump to the relevant interrupt vector is determined by the condition of the interrupt enable bit. If the enable bit is set high then the program will jump to its relevant vector; if the enable bit is zero then although the interrupt request flag is set an actual interrupt will not be generated and the program will not jump to the relevant interrupt vector. The global interrupt enable bit, if cleared to zero, will disable all interrupts.

When an interrupt is generated, the Program Counter, which stores the address of the next instruction to be executed, will be transferred onto the stack. The Program Counter will then be loaded with a new address which will be the value of the corresponding interrupt vector. The microcontroller will then fetch its next instruction from this interrupt vector. The instruction at this vector will usually be a "JMP" which will jump to another section of program which is known as the interrupt service routine. Here is located the code to control the appropriate interrupt. The interrupt service routine must be terminated with a "RETI", which retrieves the original Program Counter address from the stack and allows the microcontroller to continue with normal execution at the point where the interrupt occurred.

The various interrupt enable bits, together with their associated request flags, are shown in the accompanying diagrams with their order of priority. Some interrupt sources have their own individual vector while others share the same multi-function interrupt vector. Once an interrupt subroutine is serviced, all the other interrupts will be blocked, as the global interrupt enable bit, EMI bit will be cleared automatically. This will prevent any further interrupt nesting from occurring. However, if other interrupt requests occur during this interval, although the interrupt will not be immediately serviced, the request flag will still be recorded.

If an interrupt requires immediate servicing while the program is already in another interrupt service routine, the EMI bit should be set after entering the routine, to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the Stack Pointer is decremented. If immediate service is desired, the stack must be prevented from becoming full. In case of simultaneous requests, the accompanying diagram shows the priority that is applied. All of the interrupt request flags when set will wake-up the device if it is in SLEEP or IDLE Mode, however to prevent a wake-up from occurring the corresponding flag should be set before the device is in SLEEP or IDLE Mode.

## **External Interrupts**

The external interrupts are controlled by signal transitions on the pins INT0~INT2. An external interrupt request will take place when the external interrupt request flags, INT0F~INT2F, are set, which will occur when a transition, whose type is chosen by the edge select bits, appears on the external interrupt pins. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and respective external interrupt enable bit, INT0E~INT2E, must first be set. Additionally the correct interrupt edge type must be selected using the INTEG register to enable the external interrupt function and to choose the trigger edge type. As the external interrupt pins are pin-shared with I/O pins, they can only be configured as external interrupt pins if their external interrupt enable bit in the corresponding interrupt register has been set and the external interrupt pin is selected by the corresponding pin-shared function selection bits. The pin must also be setup as an input by setting the corresponding bit in the port control register.

When the interrupt is enabled, the stack is not full and the correct transition type appears on the external interrupt pin, a subroutine call to the external interrupt vector, will take place. When the interrupt is serviced, the external interrupt request flags, INT0F~INT2F, will be automatically reset and the EMI bit will be automatically cleared to disable other interrupts. Note that any

pull-high resistor selections on the external interrupt pins will remain valid even if the pin is used as an external interrupt input. The INTEG register is used to select the type of active edge that will trigger the external interrupt. A choice of either rising or falling or both edge types can be chosen to trigger an external interrupt. Note that the INTEG register can also be used to disable the external interrupt function.

## **Over Current Protection Interrupts**

The OCPn Interrupt is controlled by detecting the OCPn input current. An OCPn Interrupt request will take place when the OCPn Interrupt request flag, OCPnF, is set, which occurs when a large current is detected. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and OCPn Interrupt enable bit, OCPnE, must first be set. When the interrupt is enabled, the stack is not full and an over current is detected, a subroutine call to the OCPn Interrupt vector, will take place. When the interrupt is serviced, the OCPn Interrupt flag, OCPnF, will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.

## **Over Voltage Protection Interrupts**

The OVPn Interrupt is controlled by detecting the OVPn input voltage. An OVPn Interrupt request will take place when the OVPn Interrupt request flag, OVPnF, is set, which occurs when the Over Voltage Protection circuit detects an over voltage condition. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and OVPn Interrupt enable bit, OVPnE, must first be set. When the interrupt is enabled, the stack is not full and an over voltage is detected, a subroutine call to the OVPn Interrupt vector, will take place. When the interrupt is serviced, the OVPn Interrupt flag, OVPnF, will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.

### **Under Voltage Protection Interrupts**

The UVPn Interrupt is controlled by detecting the UVPn input voltage. An UVPn Interrupt request will take place when the UVPn Interrupt request flag, UVPnF, is set, which occurs when the Under Voltage Protection circuit detects an under voltage condition. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and UVPn Interrupt enable bit, UVPnE, must first be set. When the interrupt is enabled, the stack is not full and an under voltage is detected, a subroutine call to the UVPn Interrupt vector, will take place. When the interrupt is serviced, the UVPn Interrupt flag, UVPnF, will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.

### **Multi-function Interrupts**

Within this device there are two Multi-function interrupts. Unlike the other independent interrupts, these interrupts have no independent source, but rather are formed from other existing interrupt sources, namely the TM Interrupts, EEPROM interrupt and A/D Converter interrupt.

A Multi-function interrupt request will take place when any of the Multi-function interrupt request flags, MFnF are set. The Multi-function interrupt flags will be set when any of their included functions generate an interrupt request flag. To allow the program to branch to its respective interrupt vector address, when the Multi-function interrupt is enabled and the stack is not full, and either one of the interrupts contained within each of Multi-function interrupt occurs, a subroutine call to one of the Multi-function interrupt vectors will take place. When the interrupt is serviced, the related Multi-Function request flag will be automatically reset and the EMI bit will be automatically cleared to disable other interrupts.

However, it must be noted that, although the Multi-function Interrupt flags will be automatically reset when the interrupt is serviced, the request flags from the original source of the Multi-function interrupts will not be automatically reset and must be manually reset by the application program.

### **Timer Module Interrupts**

Each of the Standard Type TM and Periodic Type TM has two interrupts. All of the TM interrupts are contained within the Multi-function Interrupts. For the Standard Type TM and the Periodic Type TM, each has two interrupt request flags of STMPF, STMAF and PTMPF, PTMAF and two enable bits of STMPE, STMAE and PTMPE, PTMAE. A TM interrupt request will take place when any of the TM request flags are set, a situation which occurs when a TM comparator P or A match situation happens.

To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, respective TM Interrupt enable bit, and relevant Multi-function Interrupt enable bit, MFnE, must first be set. When the interrupt is enabled, the stack is not full and a TM comparator match situation occurs, a subroutine call to the relevant Multi-function Interrupt vector locations, will take place. When the TM interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the related MFnF flag will be automatically cleared. As the TM interrupt request flags will not be automatically cleared, they have to be cleared by the application program.

### **EEPROM Interrupt**

The EEPROM interrupt is contained within the Multi-function Interrupt. An EEPROM Interrupt request will take place when the EEPROM Interrupt request flag, DEF, is set, which occurs when an EEPROM Write cycle ends. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and EEPROM Interrupt enable bit, DEE, and associated Multi-function interrupt enable bit, must first be set. When the interrupt is enabled, the stack is not full and an EEPROM Write cycle ends, a subroutine call to the respective EEPROM Interrupt vector will take place. When the EEPROM Interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the Multi-function interrupt request flag will be also automatically cleared. As the DEF flag will not be automatically cleared, it has to be cleared by the application program.

### A/D Converter Interrupt

The A/D Converter Interrupt is also contained within the Multi-function Interrupt. The A/D Converter Interrupt is controlled by the termination of an A/D conversion process. An A/D Converter Interrupt request will take place when the A/D Converter Interrupt request flag, ADF, is set, which occurs when the A/D conversion process finishes. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and A/D Interrupt enable bit, ADE, and associated Multi-function interrupt enable bit, must first be set. When the interrupt is enabled, the stack is not full and the A/D conversion process has ended, a subroutine call to the A/D Converter Interrupt vector, will take place. When the A/D Converter interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, however only the Multi-function interrupt request flag will be also automatically cleared. As the A/D Converter Interrupt flag bit, ADF will not be automatically cleared, it has to be cleared by the application program.

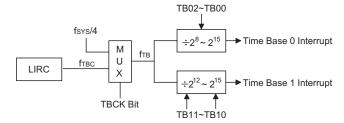

### **Time Base Interrupts**

The function of the Time Base Interrupts is to provide regular time signal in the form of an internal interrupt. They are controlled by the overflow signals from their respective timer functions. When these happens their respective interrupt request flags, TB0F or TB1F will be set. To allow the

program to branch to their respective interrupt vector addresses, the global interrupt enable bit, EMI and Time Base enable bits, TB0E or TB1E, must first be set. When the interrupt is enabled, the stack is not full and the Time Base overflows, a subroutine call to their respective vector locations will take place. When the interrupt is serviced, the respective interrupt request flag, TB0F or TB1F, will be automatically reset and the EMI bit will be cleared to disable other interrupts.

The purpose of the Time Base Interrupt is to provide an interrupt signal at fixed time periods. Their clock sources originate from the internal clock source  $f_{TB}$ . This  $f_{TB}$  input clock passes through a divider, the division ratio of which is selected by programming the appropriate bits in the TBC register to obtain longer interrupt periods whose value ranges. The clock source that generates  $f_{TB}$ , which in turn controls the Time Base interrupt period, can originate from several different sources, as shown in the System Operating Mode section.

### • TBC Register

| Bit  | 7    | 6    | 5    | 4    | 3 | 2    | 1    | 0    |
|------|------|------|------|------|---|------|------|------|
| Name | TBON | TBCK | TB11 | TB10 | _ | TB02 | TB01 | TB00 |
| R/W  | R/W  | R/W  | R/W  | R/W  | _ | R/W  | R/W  | R/W  |
| POR  | 0    | 0    | 1    | 1    | _ | 1    | 1    | 1    |

Bit 7 **TBON**: Time Base 0 and Time Base 1 Control bit

0: Disable 1: Enable

Bit 6 **TBCK**: f<sub>TB</sub> Clock Source Selection

0: f<sub>TBC</sub> 1: f<sub>SYS</sub>/4

Bit 5~4 TB11 ~ TB10: Select Time Base 1 Time-out Period

 $\begin{array}{c} 00:\ 2^{12}/f_{TB} \\ 01:\ 2^{13}/\ f_{TB} \\ 10:\ 2^{14}/f_{TB} \\ 11:\ 2^{15}/\ f_{TB} \end{array}$ 

Bit 3 Unimplemented, read as "0"

Bit 2~0 **TB02~TB00**: Select Time Base 0 Time-out Period

 $\begin{array}{l} 000:\ 2^8/f_{TB} \\ 001:\ 2^9/f_{TB} \\ 010:\ 2^{10}/f_{TB} \\ 011:\ 2^{11}/f_{TB} \\ 100:\ 2^{12}/f_{TB} \\ 101:\ 2^{13}/f_{TB} \\ 110:\ 2^{14}/f_{TB} \\ 111:\ 2^{15}/f_{TB} \end{array}$ 

### **LVD** Interrupt

An LVD Interrupt request will take place when the LVD Interrupt request flag, LVF, is set, which occurs when the Low Voltage Detector function detects a low power supply voltage. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and Low Voltage Interrupt enable bit, LVE, must first be set. When the interrupt is enabled, the stack is not full and a low voltage condition occurs, a subroutine call to the LVD Interrupt vector, will take place. When the Low Voltage Interrupt is serviced, the EMI bit will be automatically cleared to disable other interrupts, and the LVD interrupt request flag, LVF, will be also automatically cleared.

### **Serial Interface Module Interrupt**

The Serial Interface Module interrupt is also known as the SIM interrupt. A SIM interrupt request will take place when the SIM interrupt request flag, SIMF, is set, which occurs when a byte of data has been received or transmitted by the SIM interface, an I<sup>2</sup>C address match or I<sup>2</sup>C time-out occurrence. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and the Serial Interface Interrupt enable bit, SIME, must first be set. When the interrupt is enabled, the stack is not full and any of the above described situations occurs, a subroutine call to the SIM interrupt vector, will take place. When the SIM Interface Interrupt is serviced, the interrupt request flag, SIMF, will be automatically reset and the EMI bit will be cleared to disable other interrupts.

### **Interrupt Wake-up Function**

Each of the interrupt functions has the capability of waking up the microcontroller when in the SLEEP or IDLE Mode. A wake-up is generated when an interrupt request flag changes from low to high and is independent of whether the interrupt is enabled or not. Therefore, even though the device is in the SLEEP or IDLE Mode and its system oscillator stopped, situations such as external edge transitions on the external interrupt pins or a low power supply voltage may cause their respective interrupt flag to be set high and consequently generate an interrupt. Care must therefore be taken if spurious wake-up situations are to be avoided. If an interrupt wake-up function is to be disabled then the corresponding interrupt request flag should be set high before the device enters the SLEEP or IDLE Mode. The interrupt enable bits have no effect on the interrupt wake-up function.

## **Programming Considerations**

By disabling the relevant interrupt enable bits, a requested interrupt can be prevented from being serviced, however, once an interrupt request flag is set, it will remain in this condition in the interrupt register until the corresponding interrupt is serviced or until the request flag is cleared by the application program.

Where a certain interrupt is contained within a Multi-function interrupt, then when the interrupt service routine is executed, as only the Multi-function interrupt request flags, MFnF, will be automatically cleared, the individual request flag for the function needs to be cleared by the application program.

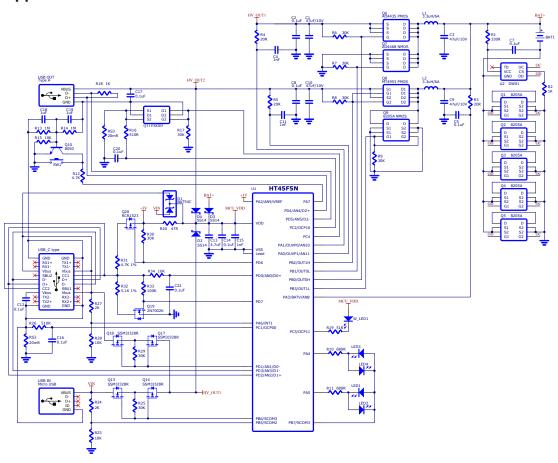

It is recommended that programs do not use the "CALL" instruction within the interrupt service subroutine. Interrupts often occur in an unpredictable manner or need to be serviced immediately. If only one stack is left and the interrupt is not well controlled, the original control sequence will be damaged once a CALL subroutine is executed in the interrupt subroutine.

Every interrupt has the capability of waking up the microcontroller when it is in SLEEP or IDLE Mode, the wake up being generated when the interrupt request flag changes from low to high. If it is required to prevent a certain interrupt from waking up the microcontroller then its respective request flag should be first set high before enter SLEEP or IDLE Mode.

As only the Program Counter is pushed onto the stack, then when the interrupt is serviced, if the contents of the accumulator, status register or other registers are altered by the interrupt service program, their contents should be saved to the memory at the beginning of the interrupt service routine. To return from an interrupt subroutine, either a RET or RETI instruction may be executed. The RETI instruction in addition to executing a return to the main program also automatically sets the EMI bit high to allow further interrupts. The RET instruction however only executes a return to the main program leaving the EMI bit in its present zero state and therefore disabling the execution of further interrupts.

# **Application Circuits**

## **Instruction Set**

#### Introduction

Central to the successful operation of any microcontroller is its instruction set, which is a set of program instruction codes that directs the microcontroller to perform certain operations. In the case of Holtek microcontroller, a comprehensive and flexible set of over 60 instructions is provided to enable programmers to implement their application with the minimum of programming overheads.

For easier understanding of the various instruction codes, they have been subdivided into several functional groupings.

## **Instruction Timing**

Most instructions are implemented within one instruction cycle. The exceptions to this are branch, call, or table read instructions where two instruction cycles are required. One instruction cycle is equal to 4 system clock cycles, therefore in the case of an 8MHz system oscillator, most instructions would be implemented within 0.5µs and branch or call instructions would be implemented within 1µs. Although instructions which require one more cycle to implement are generally limited to the JMP, CALL, RET, RETI and table read instructions, it is important to realize that any other instructions which involve manipulation of the Program Counter Low register or PCL will also take one more cycle to implement. As instructions which change the contents of the PCL will imply a direct jump to that new address, one more cycle will be required. Examples of such instructions would be "CLR PCL" or "MOV PCL, A". For the case of skip instructions, it must be noted that if the result of the comparison involves a skip operation then this will also take one more cycle, if no skip is involved then only one cycle is required.

## **Moving and Transferring Data**

The transfer of data within the microcontroller program is one of the most frequently used operations. Making use of several kinds of MOV instructions, data can be transferred from registers to the Accumulator and vice-versa as well as being able to move specific immediate data directly into the Accumulator. One of the most important data transfer applications is to receive data from the input ports and transfer data to the output ports.

### **Arithmetic Operations**

The ability to perform certain arithmetic operations and data manipulation is a necessary feature of most microcontroller applications. Within the Holtek microcontroller instruction set are a range of add and subtract instruction mnemonics to enable the necessary arithmetic to be carried out. Care must be taken to ensure correct handling of carry and borrow data when results exceed 255 for addition and less than 0 for subtraction. The increment and decrement instructions such as INC, INCA, DEC and DECA provide a simple means of increasing or decreasing by a value of one of the values in the destination specified.

### **Logical and Rotate Operation**

The standard logical operations such as AND, OR, XOR and CPL all have their own instruction within the Holtek microcontroller instruction set. As with the case of most instructions involving data manipulation, data must pass through the Accumulator which may involve additional programming steps. In all logical data operations, the zero flag may be set if the result of the operation is zero. Another form of logical data manipulation comes from the rotate instructions such as RR, RL, RRC and RLC which provide a simple means of rotating one bit right or left. Different rotate instructions exist depending on program requirements. Rotate instructions are useful for serial port programming applications where data can be rotated from an internal register into the Carry bit from where it can be examined and the necessary serial bit set high or low. Another application which rotate data operations are used is to implement multiplication and division calculations.

### **Branches and Control Transfer**

Program branching takes the form of either jumps to specified locations using the JMP instruction or to a subroutine using the CALL instruction. They differ in the sense that in the case of a subroutine call, the program must return to the instruction immediately when the subroutine has been carried out. This is done by placing a return instruction "RET" in the subroutine which will cause the program to jump back to the address right after the CALL instruction. In the case of a JMP instruction, the program simply jumps to the desired location. There is no requirement to jump back to the original jumping off point as in the case of the CALL instruction. One special and extremely useful set of branch instructions are the conditional branches. Here a decision is first made regarding the condition of a certain data memory or individual bits. Depending upon the conditions, the program will continue with the next instruction or skip over it and jump to the following instruction. These instructions are the key to decision making and branching within the program perhaps determined by the condition of certain input switches or by the condition of internal data bits.

#### **Bit Operations**

The ability to provide single bit operations on Data Memory is an extremely flexible feature of all Holtek microcontrollers. This feature is especially useful for output port bit programming where individual bits or port pins can be directly set high or low using either the "SET [m].i" or "CLR [m].i" instructions respectively. The feature removes the need for programmers to first read the 8-bit output port, manipulate the input data to ensure that other bits are not changed and then output the port with the correct new data. This read-modify-write process is taken care of automatically when these bit operation instructions are used.

### **Table Read Operations**

Data storage is normally implemented by using registers. However, when working with large amounts of fixed data, the volume involved often makes it inconvenient to store the fixed data in the Data Memory. To overcome this problem, Holtek microcontrollers allow an area of Program Memory to be setup as a table where data can be directly stored. A set of easy to use instructions provides the means by which this fixed data can be referenced and retrieved from the Program Memory.

#### Other Operations

In addition to the above functional instructions, a range of other instructions also exist such as the "HALT" instruction for Power-down operations and instructions to control the operation of the Watchdog Timer for reliable program operations under extreme electric or electromagnetic environments. For their relevant operations, refer to the functional related sections.

# **Instruction Set Summary**

The instructions related to the data memory access in the following table can be used when the desired data memory is located in Data Memory sector 0.

### **Table Conventions**

x: Bits immediate data m: Data Memory address

A: Accumulator i: 0~7 number of bits

addr: Program memory address

| Mnemonic        | Description   | Cycles            | Flag Affected        |
|-----------------|---|-------------------|----------------------|

| SWAPA [m]     | Swap nibbles of Data Memory with result in ACC  | 1                 | None          |
| HALT          | Enter power down mode   | 1                 | TO, PDF       |

Note: 1. For skip instructions, if the result of the comparison involves a skip then two cycles are required, if no skip takes place only one cycle is required.

<sup>2.</sup> Any instruction which changes the contents of the PCL will also require 2 cycles for execution.

## **Extended Instruction Set**

The extended instructions are used to support the full range address access for the data memory. When the accessed data memory is located in any data memory sector except sector 0, the extended instruction can be used to directly access the data memory instead of using the indirect addressing access. This can not only reduce the use of Flash memory space but also improve the CPU execution efficiency.

| Mnemonic        | Description   | Cycles            | Flag Affected        |
|-----------------|---|-------------------|----------------------|
| Arithmetic      |   |                   |                      |

| LSDZ [m]      | Skip if decrement Data Memory is zero   | 2 <sup>Note</sup> | None          |
| LSIZA [m]     | Skip if increment Data Memory is zero with result in ACC                                  | 2 <sup>Note</sup> | None          |
| LSDZA [m]     | Skip if decrement Data Memory is zero with result in ACC                                  | 2 <sup>Note</sup> | None          |
| Table Read    |   |                   |               |
| LTABRD [m]    | Read table (specific page) to TBLH and Data Memory  | 3 <sup>Note</sup> | None          |
| LTABRDL [m]   | Read table (last page) to TBLH and Data Memory  | 3 <sup>Note</sup> | None          |
| LITABRD [m]   | Increment table pointer TBLP first and Read table (specific page) to TBLH and Data Memory | 3 <sup>Note</sup> | None          |
| LITABRDL [m]  | Increment table pointer TBLP first and Read table (last page) to TBLH and Data Memory     | 3 <sup>Note</sup> | None          |
| Miscellaneous |   |                   |               |
| LCLR [m]      | Clear Data Memory   | 2 <sup>Note</sup> | None          |
| LSET [m]      | Set Data Memory   | 2 <sup>Note</sup> | None          |
| LSWAP [m]     | Swap nibbles of Data Memory   | 2 <sup>Note</sup> | None          |
| LSWAPA [m]    | Swap nibbles of Data Memory with result in ACC  | 2                 | None          |

Note: 1. For these extended skip instructions, if the result of the comparison involves a skip then three cycles are required, if no skip takes place two cycles is required.

<sup>2.</sup> Any extended instruction which changes the contents of the PCL register will also require three cycles for execution.

## **Instruction Definition**

ADC A,[m] Add Data Memory to ACC with Carry

Description The contents of the specified Data Memory, Accumulator and the carry flag are added.

The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC + [m] + C$ Affected flag(s) OV, Z, AC, C, SC

ADCM A,[m] Add ACC to Data Memory with Carry

Description The contents of the specified Data Memory, Accumulator and the carry flag are added.

The result is stored in the specified Data Memory.

Operation  $[m] \leftarrow ACC + [m] + C$ Affected flag(s) OV, Z, AC, C, SC

ADD A,[m] Add Data Memory to ACC

Description The contents of the specified Data Memory and the Accumulator are added.

The result is stored in the Accumulator.

 $\begin{aligned} & \text{Operation} & & & \text{ACC} \leftarrow \text{ACC} + [m] \\ & \text{Affected flag(s)} & & & \text{OV, Z, AC, C, SC} \end{aligned}$ 

**ADD A,x** Add immediate data to ACC

Description The contents of the Accumulator and the specified immediate data are added.

The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC + x$ Affected flag(s) OV, Z, AC, C, SC

ADDM A,[m] Add ACC to Data Memory

Description The contents of the specified Data Memory and the Accumulator are added.

The result is stored in the specified Data Memory.

Operation  $[m] \leftarrow ACC + [m]$ Affected flag(s) OV, Z, AC, C, SC

AND A,[m] Logical AND Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise logical AND

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "AND" [m]$ 

Affected flag(s) Z

AND A,x Logical AND immediate data to ACC

Description Data in the Accumulator and the specified immediate data perform a bit wise logical AND

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC$  "AND" x

Affected flag(s) Z

ANDM A,[m] Logical AND ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical AND

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "AND" [m]$ 

Affected flag(s) Z

CALL addr Subroutine call

Description Unconditionally calls a subroutine at the specified address. The Program Counter then

increments by 1 to obtain the address of the next instruction which is then pushed onto the stack. The specified address is then loaded and the program continues execution from this new address. As this instruction requires an additional operation, it is a two cycle instruction.

Operation Stack  $\leftarrow$  Program Counter + 1

Program Counter ← addr

Affected flag(s) None

**CLR [m]** Clear Data Memory

Description Each bit of the specified Data Memory is cleared to 0.

Operation  $[m] \leftarrow 00H$ Affected flag(s) None

CLR [m].i Clear bit of Data Memory

Description Bit i of the specified Data Memory is cleared to 0.

Operation [m].i  $\leftarrow$  0 Affected flag(s) None

**CLR WDT** Clear Watchdog Timer

Description The TO, PDF flags and the WDT are all cleared.

Operation WDT cleared

 $TO \leftarrow 0$ <br/>PDF  $\leftarrow 0$ 

Affected flag(s) TO, PDF

**CPL [m]** Complement Data Memory

Description Each bit of the specified Data Memory is logically complemented (1's complement). Bits which

previously contained a 1 are changed to 0 and vice versa.

Operation  $[m] \leftarrow \overline{[m]}$ 

Affected flag(s) Z

**CPLA [m]** Complement Data Memory with result in ACC

Description Each bit of the specified Data Memory is logically complemented (1's complement). Bits which

previously contained a 1 are changed to 0 and vice versa. The complemented result is stored in

the Accumulator and the contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m]$ 

Affected flag(s) Z

**DAA [m]** Decimal-Adjust ACC for addition with result in Data Memory

Description Convert the contents of the Accumulator value to a BCD (Binary Coded Decimal) value

resulting from the previous addition of two BCD variables. If the low nibble is greater than 9 or if AC flag is set, then a value of 6 will be added to the low nibble. Otherwise the low nibble remains unchanged. If the high nibble is greater than 9 or if the C flag is set, then a value of 6 will be added to the high nibble. Essentially, the decimal conversion is performed by adding 00H, 06H, 60H or 66H depending on the Accumulator and flag conditions. Only the C flag may be affected by this instruction which indicates that if the original BCD sum is greater than

100, it allows multiple precision decimal addition.

Operation  $[m] \leftarrow ACC + 00H$  or

 $[m] \leftarrow ACC + 06H \text{ or}$   $[m] \leftarrow ACC + 60H \text{ or}$  $[m] \leftarrow ACC + 66H$ 

Affected flag(s) C

**DEC [m]** Decrement Data Memory

Description Data in the specified Data Memory is decremented by 1.

Operation  $[m] \leftarrow [m] - 1$ 

Affected flag(s) Z

**DECA [m]** Decrement Data Memory with result in ACC

Description Data in the specified Data Memory is decremented by 1. The result is stored in the

Accumulator. The contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m] - 1$ 

Affected flag(s) Z

**HALT** Enter power down mode

Description This instruction stops the program execution and turns off the system clock. The contents of

the Data Memory and registers are retained. The WDT and prescaler are cleared. The power

down flag PDF is set and the WDT time-out flag TO is cleared.

Operation  $TO \leftarrow 0$ 

 $PDF \leftarrow 1$ 

Affected flag(s) TO, PDF

**INC [m]** Increment Data Memory

Description Data in the specified Data Memory is incremented by 1.

Operation  $[m] \leftarrow [m] + 1$ 

Affected flag(s) Z

**INCA [m]** Increment Data Memory with result in ACC

Description Data in the specified Data Memory is incremented by 1. The result is stored in the Accumulator.

The contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m] + 1$ 

Affected flag(s) Z

JMP addr Jump unconditionally

Description The contents of the Program Counter are replaced with the specified address. Program

execution then continues from this new address. As this requires the insertion of a dummy

instruction while the new address is loaded, it is a two cycle instruction.

Operation Program Counter ← addr

Affected flag(s) None

MOV A,[m] Move Data Memory to ACC

Description The contents of the specified Data Memory are copied to the Accumulator.

Operation  $ACC \leftarrow [m]$ Affected flag(s) None

**MOV A,x** Move immediate data to ACC

Description The immediate data specified is loaded into the Accumulator.

Operation  $ACC \leftarrow x$ Affected flag(s) None

**MOV [m],A** Move ACC to Data Memory

Description The contents of the Accumulator are copied to the specified Data Memory.

Operation  $[m] \leftarrow ACC$ Affected flag(s) None

**NOP** No operation

Description No operation is performed. Execution continues with the next instruction.

Operation No operation
Affected flag(s) None

OR A,[m] Logical OR Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise

logical OR operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "OR" [m]$ 

Affected flag(s) Z

**OR A,x** Logical OR immediate data to ACC

Description Data in the Accumulator and the specified immediate data perform a bitwise logical OR

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "OR" x$ 

Affected flag(s) Z

ORM A,[m] Logical OR ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical OR

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "OR" [m]$ 

Affected flag(s) Z

**RET** Return from subroutine

Description The Program Counter is restored from the stack. Program execution continues at the restored

address.

Operation Program Counter ← Stack

Affected flag(s) None

**RET A,x** Return from subroutine and load immediate data to ACC

Description The Program Counter is restored from the stack and the Accumulator loaded with the specified

immediate data. Program execution continues at the restored address.

Operation Program Counter ← Stack

 $ACC \leftarrow x$ 

Affected flag(s) None

**RETI** Return from interrupt

Description The Program Counter is restored from the stack and the interrupts are re-enabled by setting the

EMI bit. EMI is the master interrupt global enable bit. If an interrupt was pending when the RETI instruction is executed, the pending Interrupt routine will be processed before returning

to the main program.

Operation Program Counter ← Stack

 $EMI \leftarrow 1$ 

Affected flag(s) None

RL [m] Rotate Data Memory left

Description The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0.

Operation  $[m].(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $[m].0 \leftarrow [m].7$ 

Affected flag(s) None

Rotate Data Memory left with result in ACC RLA [m]

The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0. Description

The rotated result is stored in the Accumulator and the contents of the Data Memory remain

unchanged.

Operation  $ACC.(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $ACC.0 \leftarrow [m].7$ 

Affected flag(s) None

Rotate Data Memory left through Carry RLC [m]

The contents of the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7 Description

replaces the Carry bit and the original carry flag is rotated into bit 0.

Operation  $[m].(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $[m].0 \leftarrow C$ 

 $C \leftarrow [m].7$ 

C Affected flag(s)

RLCA [m] Rotate Data Memory left through Carry with result in ACC

Description Data in the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7 replaces the

Carry bit and the original carry flag is rotated into the bit 0. The rotated result is stored in the

Accumulator and the contents of the Data Memory remain unchanged.

Operation  $ACC.(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $ACC.0 \leftarrow C$ 

 $C \leftarrow [m].7$ 

Affected flag(s) C

RR [m] Rotate Data Memory right

The contents of the specified Data Memory are rotated right by 1 bit with bit 0 rotated into bit 7. Description

Operation  $[m].i \leftarrow [m].(i+1); (i=0\sim6)$ 

 $[m].7 \leftarrow [m].0$ 

Affected flag(s) None

RRA [m] Rotate Data Memory right with result in ACC

Description Data in the specified Data Memory is rotated right by 1 bit with bit 0

rotated into bit 7. The rotated result is stored in the Accumulator and the contents of the

Data Memory remain unchanged.

 $ACC.i \leftarrow [m].(i+1); (i=0\sim6)$ Operation

 $ACC.7 \leftarrow [m].0$ 

Affected flag(s) None

RRC [m] Rotate Data Memory right through Carry

The contents of the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0 Description

replaces the Carry bit and the original carry flag is rotated into bit 7.

Operation  $[m].i \leftarrow [m].(i+1); (i=0\sim6)$ 

[m].7 ← C

 $C \leftarrow [m].0$ 

Affected flag(s) C

RRCA [m] Rotate Data Memory right through Carry with result in ACC

Description Data in the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0 replaces

the Carry bit and the original carry flag is rotated into bit 7. The rotated result is stored in the

Accumulator and the contents of the Data Memory remain unchanged.

Operation ACC.i  $\leftarrow$  [m].(i+1); (i=0 $\sim$ 6)

 $ACC.7 \leftarrow C$  $C \leftarrow [m].0$ 

Affected flag(s) C

SBC A,[m] Subtract Data Memory from ACC with Carry

Description The contents of the specified Data Memory and the complement of the carry flag are

subtracted from the Accumulator. The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is

positive or zero, the C flag will be set to 1.

Operation  $ACC \leftarrow ACC - [m] - \overline{C}$ Affected flag(s) OV, Z, AC, C, SC, CZ

**SBC A, x** Subtract immediate data from ACC with Carry

Description The immediate data and the complement of the carry flag are subtracted from the

Accumulator. The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is positive or zero, the C flag

will be set to 1.

Operation  $ACC \leftarrow ACC - [m] - \overline{C}$ Affected flag(s) OV, Z, AC, C, SC, CZ

SBCM A,[m] Subtract Data Memory from ACC with Carry and result in Data Memory

Description The contents of the specified Data Memory and the complement of the carry flag are

subtracted from the Accumulator. The result is stored in the Data Memory. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is

positive or zero, the C flag will be set to 1.

Operation  $[m] \leftarrow ACC - [m] - C$ Affected flag(s) OV, Z, AC, C, SC, CZ

**SDZ [m]** Skip if decrement Data Memory is 0

Description The contents of the specified Data Memory are first decremented by 1. If the result is 0 the

following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program

proceeds with the following instruction.

Operation  $[m] \leftarrow [m] - 1$ 

Skip if [m]=0

Affected flag(s) None

**SDZA [m]** Skip if decrement Data Memory is zero with result in ACC

Description The contents of the specified Data Memory are first decremented by 1. If the result is 0, the

following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy

instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0,

the program proceeds with the following instruction.

Operation  $ACC \leftarrow [m] - 1$ 

Skip if ACC=0

Affected flag(s) None

SET [m] Set Data Memory

Description Each bit of the specified Data Memory is set to 1.

Operation  $[m] \leftarrow FFH$ Affected flag(s) None

SET [m].i Set bit of Data Memory

Description Bit i of the specified Data Memory is set to 1.

 $\begin{array}{ll} \text{Operation} & \quad [m].i \leftarrow 1 \\ \text{Affected flag(s)} & \quad \text{None} \end{array}$ 

**SIZ [m]** Skip if increment Data Memory is 0

Description The contents of the specified Data Memory are first incremented by 1. If the result is 0, the

following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program

proceeds with the following instruction.

Operation  $[m] \leftarrow [m] + 1$ 

Skip if [m]=0

Affected flag(s) None

**SIZA [m]** Skip if increment Data Memory is zero with result in ACC

Description The contents of the specified Data Memory are first incremented by 1. If the result is 0, the

following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not

0 the program proceeds with the following instruction.

Operation  $ACC \leftarrow [m] + 1$ 

Skip if ACC=0

Affected flag(s) None

**SNZ [m].i** Skip if bit i of Data Memory is not 0

Description If bit i of the specified Data Memory is not 0, the following instruction is skipped. As this

requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is 0 the program proceeds with the following instruction.

Operation Skip if  $[m].i \neq 0$ 

Affected flag(s) None

**SNZ [m]** Skip if Data Memory is not 0

Description The contents of the specified Data Memory are read out and then written back to the specified

Data Memory again. If the specified Data Memory is not 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is 0 the program proceeds with the following

instruction.

Operation Skip if  $[m] \neq 0$ 

Affected flag(s) None

**SUB A,[m]** Subtract Data Memory from ACC

Description The specified Data Memory is subtracted from the contents of the Accumulator. The result is

stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be

cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

 $\label{eq:operation} \begin{aligned} & \text{Operation} & & \text{ACC} \leftarrow \text{ACC} - [m] \\ & \text{Affected flag(s)} & & \text{OV, Z, AC, C, SC, CZ} \end{aligned}$ 

**SUBM A,[m]** Subtract Data Memory from ACC with result in Data Memory

Description The specified Data Memory is subtracted from the contents of the Accumulator. The result is

stored in the Data Memory. Note that if the result of subtraction is negative, the C flag will be

cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

 $\begin{aligned} & \text{Operation} & & [m] \leftarrow ACC - [m] \\ & \text{Affected flag(s)} & & \text{OV, Z, AC, C, SC, CZ} \end{aligned}$ 

**SUB A,x** Subtract immediate data from ACC

Description The immediate data specified by the code is subtracted from the contents of the Accumulator.

The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

Operation  $ACC \leftarrow ACC - x$ Affected flag(s) OV, Z, AC, C, SC, CZ

**SWAP [m]** Swap nibbles of Data Memory

Description The low-order and high-order nibbles of the specified Data Memory are interchanged.

Operation  $[m].3\sim[m].0 \leftrightarrow [m].7\sim[m].4$ 

Affected flag(s) None

**SWAPA [m]** Swap nibbles of Data Memory with result in ACC

Description The low-order and high-order nibbles of the specified Data Memory are interchanged. The

result is stored in the Accumulator. The contents of the Data Memory remain unchanged.

Operation ACC.3 $\sim$ ACC.0  $\leftarrow$  [m].7 $\sim$ [m].4

 $ACC.7 \sim ACC.4 \leftarrow [m].3 \sim [m].0$ 

Affected flag(s) None

**SZ [m]** Skip if Data Memory is 0

Description The contents of the specified Data Memory are read out and then written back to the specified

Data Memory again. If the contents of the specified Data Memory is 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program proceeds

with the following instruction.

Operation Skip if [m]=0

Affected flag(s) None

**SZA [m]** Skip if Data Memory is 0 with data movement to ACC

Description The contents of the specified Data Memory are copied to the Accumulator. If the value is zero,

the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the

program proceeds with the following instruction.

Operation  $ACC \leftarrow [m]$ 

Skip if [m]=0

Affected flag(s) None

**SZ [m].i** Skip if bit i of Data Memory is 0

Description If bit i of the specified Data Memory is 0, the following instruction is skipped. As this requires

the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0, the program proceeds with the following instruction.

Operation Skip if [m].i=0

Affected flag(s) None

Rev. 1.50 181 October 26, 2023

**TABRD [m]** Read table (specific page) to TBLH and Data Memory

Description The low byte of the program code (specific page) addressed by the table pointer (TBLP and

TBHP) is moved to the specified Data Memory and the high byte moved to TBLH.

Operation  $[m] \leftarrow program code (low byte)$ 

TBLH ← program code (high byte)

Affected flag(s) None

**TABRDL [m]** Read table (last page) to TBLH and Data Memory

Description The low byte of the program code (last page) addressed by the table pointer (TBLP) is moved

to the specified Data Memory and the high byte moved to TBLH.

Operation  $[m] \leftarrow \text{program code (low byte)}$ 

TBLH ← program code (high byte)

Affected flag(s) None

**ITABRD [m]** Increment table pointer low byte first and read table (specific page) to TBLH and Data

Memory

Description Increment table pointer low byte, TBLP, first and then the program code (specific page)

addressed by the table pointer (TBHP and TBLP) is moved to the specified Data Memory and

the high byte moved to TBLH.

Operation  $[m] \leftarrow \text{program code (low byte)}$ 

TBLH ← program code (high byte)

Affected flag(s) None

**ITABRDL [m]** Increment table pointer low byte first and read table (last page) to TBLH and Data Memory

Description Increment table pointer low byte, TBLP, first and then the low byte of the program code

(last page) addressed by the table pointer (TBLP) is moved to the specified Data Memory and

the high byte moved to TBLH.

Operation  $[m] \leftarrow program code (low byte)$ 

TBLH ← program code (high byte)

Affected flag(s) None

**XOR A,[m]** Logical XOR Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise logical XOR

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "XOR" [m]$ 

Affected flag(s) Z

**XORM A,[m]** Logical XOR ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical XOR

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "XOR" [m]$ 

Affected flag(s) Z

**XOR A,x** Logical XOR immediate data to ACC

Description Data in the Accumulator and the specified immediate data perform a bitwise logical XOR

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "XOR" x$ 

Affected flag(s) Z

Rev. 1.50 182 October 26, 2023

## **Extended Instruction Definition**

The extended instructions are used to directly access the data stored in any data memory sections.

**LADC A,[m]** Add Data Memory to ACC with Carry

Description The contents of the specified Data Memory, Accumulator and the carry flag are added.

The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC + [m] + C$ Affected flag(s) OV, Z, AC, C, SC

**LADCM A,[m]** Add ACC to Data Memory with Carry

Description The contents of the specified Data Memory, Accumulator and the carry flag are added.

The result is stored in the specified Data Memory.

 $\begin{aligned} & \text{Operation} & & & [m] \leftarrow ACC + [m] + C \\ & \text{Affected flag(s)} & & \text{OV, Z, AC, C, SC} \end{aligned}$ 

**LADD A,[m]** Add Data Memory to ACC

Description The contents of the specified Data Memory and the Accumulator are added.

The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC + [m]$ Affected flag(s) OV, Z, AC, C, SC

**LADDM A,[m]** Add ACC to Data Memory

Description The contents of the specified Data Memory and the Accumulator are added.

The result is stored in the specified Data Memory.

Operation  $[m] \leftarrow ACC + [m]$ Affected flag(s) OV, Z, AC, C, SC

**LAND A,[m]** Logical AND Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise logical AND

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "AND" [m]$ 

Affected flag(s) Z

**LANDM A,[m]** Logical AND ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical AND

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "AND" [m]$ 

Affected flag(s) Z

LCLR [m] Clear Data Memory

Description Each bit of the specified Data Memory is cleared to 0.

Operation  $[m] \leftarrow 00H$ Affected flag(s) None

LCLR [m].i Clear bit of Data Memory

Description Bit i of the specified Data Memory is cleared to 0.

Operation [m].i  $\leftarrow$  0 Affected flag(s) None

LCPL [m] Complement Data Memory

Description Each bit of the specified Data Memory is logically complemented (1's complement). Bits which

previously contained a 1 are changed to 0 and vice versa.

Operation  $[m] \leftarrow [m]$ 

Affected flag(s) Z

**LCPLA [m]** Complement Data Memory with result in ACC

Description Each bit of the specified Data Memory is logically complemented (1's complement). Bits which

previously contained a 1 are changed to 0 and vice versa. The complemented result is stored in

the Accumulator and the contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m]$ 

Affected flag(s) Z

**LDAA [m]** Decimal-Adjust ACC for addition with result in Data Memory

Description Convert the contents of the Accumulator value to a BCD (Binary Coded Decimal) value

resulting from the previous addition of two BCD variables. If the low nibble is greater than 9 or if AC flag is set, then a value of 6 will be added to the low nibble. Otherwise the low nibble remains unchanged. If the high nibble is greater than 9 or if the C flag is set, then a value of 6 will be added to the high nibble. Essentially, the decimal conversion is performed by adding 00H, 06H, 60H or 66H depending on the Accumulator and flag conditions. Only the C flag may be affected by this instruction which indicates that if the original BCD sum is greater than

100, it allows multiple precision decimal addition.

Operation  $[m] \leftarrow ACC + 00H$  or

 $[m] \leftarrow ACC + 06H \text{ or}$   $[m] \leftarrow ACC + 60H \text{ or}$  $[m] \leftarrow ACC + 66H$ 

Affected flag(s)

**LDEC [m]** Decrement Data Memory

Description Data in the specified Data Memory is decremented by 1.

Operation  $[m] \leftarrow [m] - 1$ 

Affected flag(s) Z

**LDECA [m]** Decrement Data Memory with result in ACC

Description Data in the specified Data Memory is decremented by 1. The result is stored in the

Accumulator. The contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m] - 1$ 

Affected flag(s) Z

**LINC [m]** Increment Data Memory

Description Data in the specified Data Memory is incremented by 1.

Operation  $[m] \leftarrow [m] + 1$ 

Affected flag(s) Z

**LINCA [m]** Increment Data Memory with result in ACC

Description Data in the specified Data Memory is incremented by 1. The result is stored in the Accumulator.

The contents of the Data Memory remain unchanged.

Operation  $ACC \leftarrow [m] + 1$ 

Affected flag(s) Z

Rev. 1.50 184 October 26, 2023

LMOV A,[m] Move Data Memory to ACC

The contents of the specified Data Memory are copied to the Accumulator. Description

Operation  $ACC \leftarrow [m]$ Affected flag(s) None

LMOV [m],A Move ACC to Data Memory

Description The contents of the Accumulator are copied to the specified Data Memory.

Operation  $[m] \leftarrow ACC$ Affected flag(s) None

LOR A,[m] Logical OR Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise

logical OR operation. The result is stored in the Accumulator.

 $ACC \leftarrow ACC "OR" [m]$ Operation

Affected flag(s) Z

LORM A,[m] Logical OR ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical OR

operation. The result is stored in the Data Memory.

 $[m] \leftarrow ACC "OR" [m]$ Operation

Affected flag(s) Z

LRL [m] Rotate Data Memory left

Description The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0.

Operation  $[m].(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $[m].0 \leftarrow [m].7$ 

Affected flag(s) None

LRLA [m] Rotate Data Memory left with result in ACC

The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0. Description

The rotated result is stored in the Accumulator and the contents of the Data Memory remain

unchanged.

Operation  $ACC.(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $ACC.0 \leftarrow [m].7$ 

Affected flag(s) None

LRLC [m] Rotate Data Memory left through Carry

Description The contents of the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7

replaces the Carry bit and the original carry flag is rotated into bit 0.

Operation  $[m].(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $[m].0 \leftarrow C$  $C \leftarrow [m].7$ 

Affected flag(s)

LRLCA [m] Rotate Data Memory left through Carry with result in ACC

Data in the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7 replaces the Description

Carry bit and the original carry flag is rotated into the bit 0. The rotated result is stored in the

Accumulator and the contents of the Data Memory remain unchanged.

Operation  $ACC.(i+1) \leftarrow [m].i; (i=0\sim6)$ 

 $ACC.0 \leftarrow C$  $C \leftarrow [m].7$ 

Affected flag(s) C

LRR [m] Rotate Data Memory right

Description The contents of the specified Data Memory are rotated right by 1 bit with bit 0 rotated into bit 7.

Operation [m].i  $\leftarrow$  [m].(i+1); (i=0 $\sim$ 6)

 $[m].7 \leftarrow [m].0$ 

Affected flag(s) None

**LRRA [m]** Rotate Data Memory right with result in ACC

Description Data in the specified Data Memory is rotated right by 1 bit with bit 0

rotated into bit 7. The rotated result is stored in the Accumulator and the contents of the

Data Memory remain unchanged.

Operation ACC.i  $\leftarrow$  [m].(i+1); (i=0 $\sim$ 6)

 $ACC.7 \leftarrow [m].0$ 

Affected flag(s) None

LRRC [m] Rotate Data Memory right through Carry

Description The contents of the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0

replaces the Carry bit and the original carry flag is rotated into bit 7.

Operation  $[m].i \leftarrow [m].(i+1); (i=0\sim6)$ 

 $\begin{matrix} [m].7 \leftarrow C \\ C \leftarrow [m].0 \end{matrix}$ 

Affected flag(s) C

**LRRCA [m]** Rotate Data Memory right through Carry with result in ACC

Description Data in the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0 replaces

the Carry bit and the original carry flag is rotated into bit 7. The rotated result is stored in the

Accumulator and the contents of the Data Memory remain unchanged.

Operation ACC.i  $\leftarrow$  [m].(i+1); (i=0 $\sim$ 6)

 $ACC.7 \leftarrow C$ 

 $C \leftarrow [m].0$ 

Affected flag(s) C

**LSBC A,[m]** Subtract Data Memory from ACC with Carry

Description The contents of the specified Data Memory and the complement of the carry flag are

subtracted from the Accumulator. The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is

positive or zero, the C flag will be set to 1.

Operation  $ACC \leftarrow ACC - [m] - \overline{C}$ Affected flag(s) OV, Z, AC, C, SC, CZ

**LSBCM A,[m]** Subtract Data Memory from ACC with Carry and result in Data Memory

Description The contents of the specified Data Memory and the complement of the carry flag are

subtracted from the Accumulator. The result is stored in the Data Memory. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is

positive or zero, the C flag will be set to 1.

Operation  $[m] \leftarrow ACC - [m] - \overline{C}$ Affected flag(s) OV, Z, AC, C, SC, CZ

Rev. 1.50 186 October 26, 2023

**LSDZ [m]** Skip if decrement Data Memory is 0

Description The contents of the specified Data Memory are first decremented by 1. If the result is 0 the

following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is not 0 the program

proceeds with the following instruction.

Operation  $[m] \leftarrow [m] - 1$ 

Skip if [m]=0

Affected flag(s) None

**LSDZA [m]** Skip if decrement Data Memory is zero with result in ACC

Description The contents of the specified Data Memory are first decremented by 1. If the result is 0, the

following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is

not 0, the program proceeds with the following instruction.

Operation  $ACC \leftarrow [m] - 1$ 

Skip if ACC=0

Affected flag(s) None

Description Bit i of the specified Data Memory is set to 1.

Operation  $[m].i \leftarrow 1$ Affected flag(s) None

**LSIZ** [m] Skip if increment Data Memory is 0

Description The contents of the specified Data Memory are first incremented by 1. If the result is 0, the

following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is not 0 the program

proceeds with the following instruction.

Operation  $[m] \leftarrow [m] + 1$ 

Skip if [m]=0

Affected flag(s) None

**LSIZA [m]** Skip if increment Data Memory is zero with result in ACC

Description The contents of the specified Data Memory are first incremented by 1. If the result is 0, the

following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is

not 0 the program proceeds with the following instruction.

Operation  $ACC \leftarrow [m] + 1$ 

Skip if ACC=0

Affected flag(s) None

**LSNZ [m].i** Skip if bit i of Data Memory is not 0

Description If bit i of the specified Data Memory is not 0, the following instruction is skipped. As this

requires the insertion of a dummy instruction while the next instruction is fetched, it is a three

cycle instruction. If the result is 0 the program proceeds with the following instruction.

Operation Skip if  $[m].i \neq 0$ 

Affected flag(s) None

**LSNZ [m]** Skip if Data Memory is not 0

Description The contents of the specified Data Memory are read out and then written to the specified Data

Memory again. If the content of the specified Data Memory is not 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is 0 the program proceeds with the following

instruction.

Operation Skip if  $[m] \neq 0$ 

Affected flag(s) None

**LSUB A,[m]** Subtract Data Memory from ACC

Description The specified Data Memory is subtracted from the contents of the Accumulator. The result is

stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be

cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

 $\begin{array}{ll} \text{Operation} & \text{ACC} \leftarrow \text{ACC} - [m] \\ \text{Affected flag(s)} & \text{OV, Z, AC, C, SC, CZ} \\ \end{array}$ 

**LSUBM A,[m]** Subtract Data Memory from ACC with result in Data Memory

Description The specified Data Memory is subtracted from the contents of the Accumulator. The result is

stored in the Data Memory. Note that if the result of subtraction is negative, the C flag will be

cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

 $\begin{array}{ll} \text{Operation} & [m] \leftarrow \text{ACC} - [m] \\ \text{Affected flag(s)} & \text{OV, Z, AC, C, SC, CZ} \\ \end{array}$ 

**LSWAP [m]** Swap nibbles of Data Memory

Description The low-order and high-order nibbles of the specified Data Memory are interchanged.

Operation [m].3 $\sim$ [m].0  $\leftrightarrow$  [m].7 $\sim$ [m].4

Affected flag(s) None

**LSWAPA [m]** Swap nibbles of Data Memory with result in ACC

Description The low-order and high-order nibbles of the specified Data Memory are interchanged. The

result is stored in the Accumulator. The contents of the Data Memory remain unchanged.

Operation ACC.3 $\sim$ ACC.0  $\leftarrow$  [m].7 $\sim$ [m].4

 $ACC.7 \sim ACC.4 \leftarrow [m].3 \sim [m].0$ 

Affected flag(s) None

**LSZ [m]** Skip if Data Memory is 0

Description The contents of the specified Data Memory are read out and then written to the specified Data

Memory again. If the contents of the specified Data Memory is 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is not 0 the program proceeds with the

following instruction.

Operation Skip if [m]=0

Affected flag(s) None

**LSZA [m]** Skip if Data Memory is 0 with data movement to ACC

Description The contents of the specified Data Memory are copied to the Accumulator. If the value is zero,

the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is not 0 the

program proceeds with the following instruction.

Operation  $ACC \leftarrow [m]$ 

Skip if [m]=0

Affected flag(s) None

Rev. 1.50 188 October 26, 2023

**LSZ [m].i** Skip if bit i of Data Memory is 0

Description If bit i of the specified Data Memory is 0, the following instruction is skipped. As this requires

the insertion of a dummy instruction while the next instruction is fetched, it is a three cycle instruction. If the result is not 0, the program proceeds with the following instruction.

Operation Skip if [m].i=0

Affected flag(s) None

**LTABRD [m]** Read table (specific page) to TBLH and Data Memory

Description The low byte of the program code (specific page) addressed by the table pointer (TBHP and

TBLP) is moved to the specified Data Memory and the high byte moved to TBLH.

Operation  $[m] \leftarrow program code (low byte)$ 

TBLH ← program code (high byte)

Affected flag(s) None

**LTABRDL [m]** Read table (last page) to TBLH and Data Memory

Description The low byte of the program code (last page) addressed by the table pointer (TBLP) is moved

to the specified Data Memory and the high byte moved to TBLH.

Operation  $[m] \leftarrow program code (low byte)$ 

TBLH ← program code (high byte)

Affected flag(s) None

**LITABRD [m]** Increment table pointer low byte first and read table (specific page) to TBLH and Data

Memory

Description Increment table pointer low byte, TBLP, first and then the program code (specific page)

addressed by the table pointer (TBHP and TBLP) is moved to the specified Data Memory and

the high byte moved to TBLH.

Operation  $[m] \leftarrow program code (low byte)$ 

TBLH ← program code (high byte)

Affected flag(s) None

**LITABRDL [m]** Increment table pointer low byte first and read table (last page) to TBLH and Data Memory

Description Increment table pointer low byte, TBLP, first and then the low byte of the program code

(last page) addressed by the table pointer (TBLP) is moved to the specified Data Memory and

the high byte moved to TBLH.

Operation  $[m] \leftarrow \text{program code (low byte)}$ 

TBLH ← program code (high byte)

Affected flag(s) None

**LXOR A.[m]** Logical XOR Data Memory to ACC

Description Data in the Accumulator and the specified Data Memory perform a bitwise logical XOR

operation. The result is stored in the Accumulator.

Operation  $ACC \leftarrow ACC "XOR" [m]$ 

Affected flag(s) Z

**LXORM A,[m]** Logical XOR ACC to Data Memory

Description Data in the specified Data Memory and the Accumulator perform a bitwise logical XOR

operation. The result is stored in the Data Memory.

Operation  $[m] \leftarrow ACC "XOR" [m]$ 

Affected flag(s) Z
